DIAGNOSIS AND TREATMENT OF GOUT AND GOUTY ARTHRITIS

PHILIP S. HENCH, M.D.

ROCHESTER, MINN.

Contrary to general belief, gout is fairly common in the United States; but it is frequently unrecognized. Most patients with gouty arthritis have their disease for several years and endure a number of attacks before a correct diagnosis is made.¹ This is unfortunate because of the various articular diseases, acute gouty arthritis is one of the most responsive to treatment. Hence the most important point in the treatment of gout and gouty arthritis is its recognition. The diagnosis of gout must therefore be considered in some detail.²

Gout is a disease of unknown etiology characterized chiefly by (1) arthritis, which is at first acute and recurrent, each attack being followed by complete symptomatic remission, but which later tends to become chronic; (2) supposed abnormality in the renal excretion of uric acid, the end product of purine metabolism; (3) hyperuricemia, which is usually transient at first but later generally becomes chronic; (4) eventual deposits of sodium urate crystals in articular, periarticular and subcutaneous tissues, sometimes also in kidneys and urinary tract; (5) frequent terminal vascular lesions in the kidneys, sometimes also in the heart and brain.

Recent opinions³ are that gout results from (1) some endocrine deficiency, (2) abnormal renal insensitivity to urates, (3) selective renal insufficiency for urates alone, (4) a "storm in the vegetative nervous system," a functional disturbance involving the renal or the thoracic sympathetic nerves, or (5) an allergic reaction to proteins, not necessarily to exogenous proteins derived from foods rich in purine (fig. 1), but also to proteins from certain nonpurine foods as well as to endogenous proteins, tissue substances formed after injuries, vasomotor disturbances or operations.

Gout and gouty arthritis are not synonymous; the latter is merely the dominant symptom of gout. The arthritis and the other principal features of gout (hyperuricemia, tophi, late renal and cardiovascular

complications) are only the outward signs of some underlying chemical or metabolic abnormality of which little is known. This disturbance, the gout per se or the constitutional gouty state, is in symptomless operation for some time before acute arthritis first appears, and it is this fundamental abnormality which under suitable provocation gives rise to the subsequent appearance of the classic symptoms.

THE PATTERN OF GOUTY ARTHRITIS; ITS RELATION TO OTHER FEATURES

Gout can best be studied by noting the relationship of its other features to the pattern of gouty arthritis (fig. 2). The larval stage of gout is that period of the disease prior to the first attack of gouty arthritis. During this stage of gout the body is being unobtrusively conditioned for subsequent events, but little is known about the chemical or histologic abnormalities which are then transpiring. This larval or prearthritic stage of gout is generally, but not always, symptomless; sometimes it is accompanied by transient but definite hyperuricemia of varying intensity, and in a few cases it is characterized by the appearance of subcutaneous tophi or of renal urate stones or gravel, tophi of the urinary tract, which may be discovered even before the first articular attack.

The first attack of acute gouty arthritis sometimes occurs in a young person but usually affects persons, generally men, who are more than 35 or 40 years of age; it appears suddenly, lasts from three to ten or more days and then disappears completely. In about 60 per cent of the cases¹ it affects a great toe (podagra), but it may affect an instep, ankle, knee or other peripheral joint, and the great toes may long be unaffected. Therefore a diagnosis of gout must not be discarded just because podagra is absent. The second attack usually occurs after a year or so and may affect the joint previously involved or a new one; it may or may not be more severe and last longer than the first attack, and it also disappears completely. Sooner or later the tempo and severity of the disease generally increase; attacks may come semiannually (often in spring and fall) or more frequently. Early attacks are generally monarticular and afebrile; later attacks are often polyarticular and may be febrile (temperature of 102 F. or more). Although certain roentgenologic changes may appear and remain after several acute attacks, in the first stage of the disease joints recover full symptomless function.

From three to forty (average twelve) years after the first attack the second great stage of articular gout occurs, that of chronic gouty arthritis, when the joints no longer recover completely but some stiffness, pain or deformity remains; in this stage acute exacerbations are superimposed on the residual chronic gouty arthritis.

From the Division of Medicine, the Mayo Clinic.

2. Hench, P. S.: The Diagnosis of Gout and Gouty Arthritis. *J. Lab. & Clin. Med.* 22: 48-55 (Oct.) 1936; Chronic Arthritis; ³ A Clinic on Some Diseases of the Joints; ⁴ Comments on the Diagnosis and Management of Gout in Certain Parts of the United States; ⁵ Hench, Vanzant and Nomland; ⁶ Hench and Darnall.

3. Hench, P. S.: Chronic Arthritis: Chronic Infectious Arthritis, Chronic Senescent Arthritis, Gout, in *Modern Medical Therapy in General Practice*, Baltimore, Williams & Wilkins Company, 1940, pp. 3359-3384.

Thus the pattern of classic gouty arthritis can be divided into two great stages comprising four phases (fig. 2). Stage 1 is that of acute recurrent gouty arthritis; stage 2 is that of chronic gouty arthritis. Phase 1 of stage 1 is that of the early, less severe and generally monarticular attacks. In this phase hyperuricemia is often present but is frequently absent not only between but during acute attacks. Subcutaneous tophi and areas of erosion in roentgenograms which are indicative of osseous tophi are almost always absent in this phase and should not be expected. Phase 2 comprises the later, generally more severe and longer attacks, which may be febrile, are often polyarticular and are associated with a more definite and persistent hyperuricemia but are still followed by complete symptomatic remissions. In this phase subcutaneous and osseous tophi are more frequent but still present in only about 25 to 35 per cent of the cases.

Fig. 1.—At the sign of a split shoe suspect gout. Excesses of alcoholies and purines are not the cause of gout, but they may cause acute gouty arthritis, the dominant symptom of gout.

In phase 3, which is the first phase of stage 2, early chronic gouty arthritis with acute attacks and incomplete remissions appears. In this phase hyperuricemia is almost always present in untreated patients but may be made to disappear, at least temporarily, under proper treatment. In this phase subcutaneous tophi on the ears, elbows and around joints are almost always present and may be multiple and ulcerating, and osseous tophi of the hands or feet, but rarely elsewhere, are commonly present. Phase 4, the second phase of stage 2, is the final stage of the disease, characterized by a relatively painless chronic gouty arthritis; hyperuricemia and multiple tophi almost always are present.

When active gout develops early in life it may reach stage 2 in middle life, but when the first symptoms of gout develop in middle or late life it frequently does not progress to stage 2 and the patient may die of some unrelated condition, perhaps at normal expectancy.

Gouty nephritis (nephrosclerosis with urate deposits and foreign body reactions in renal parenchyma) and renal colic from urate gravel or stones (urinary tophi) rarely manifest themselves in phase 1, occasionally appear in phase 2, and are not uncommon in phases 3 and 4; they are present in about 10 to 20 per cent of the total cases of gout. Aside from these renal lesions the only other valid examples of visceral gout are found in the cardiovascular system; degenerative vascular disease may complicate late gout and cause death by coronary or cerebral vascular accidents. These vascular lesions are nonspecific and do not contain urates, but intracardiac tophi have been seen,⁴ although they are rare. For reasons that have been given elsewhere³ I have rejected the conception of irregular as opposed to classic gout.

DIAGNOSIS OF GOUT AND GOUTY ARTHRITIS

When a patient has had several attacks and has had the disease long enough for some of the so-called diagnostic features, podagra, hyperuricemia, subcutaneous and osseous tophi, to develop, the diagnosis should not be difficult even for physicians who are not particularly "gout conscious." Many absolutely typical cases, however, are not being diagnosed correctly by physicians who, never thinking of gout, fail to discover the hyperuricemia and tophi which are almost crying for recognition. Unfortunately for the early diagnosis of gout these "diagnostic features" do not appear in many, perhaps in most, cases until rather late in the disease. Indeed in some cases some of them never appear. Of any physician's total cases of gout in all stages subcutaneous tophi will be found in only about 50 per cent, areas of erosion as demonstrated in the roentgenogram in only about 30 per cent, and hyperuricemia in about 75 per cent.¹ Podagra will be found to be present at some time or other in about 80 per cent, but not necessarily in the first attack.

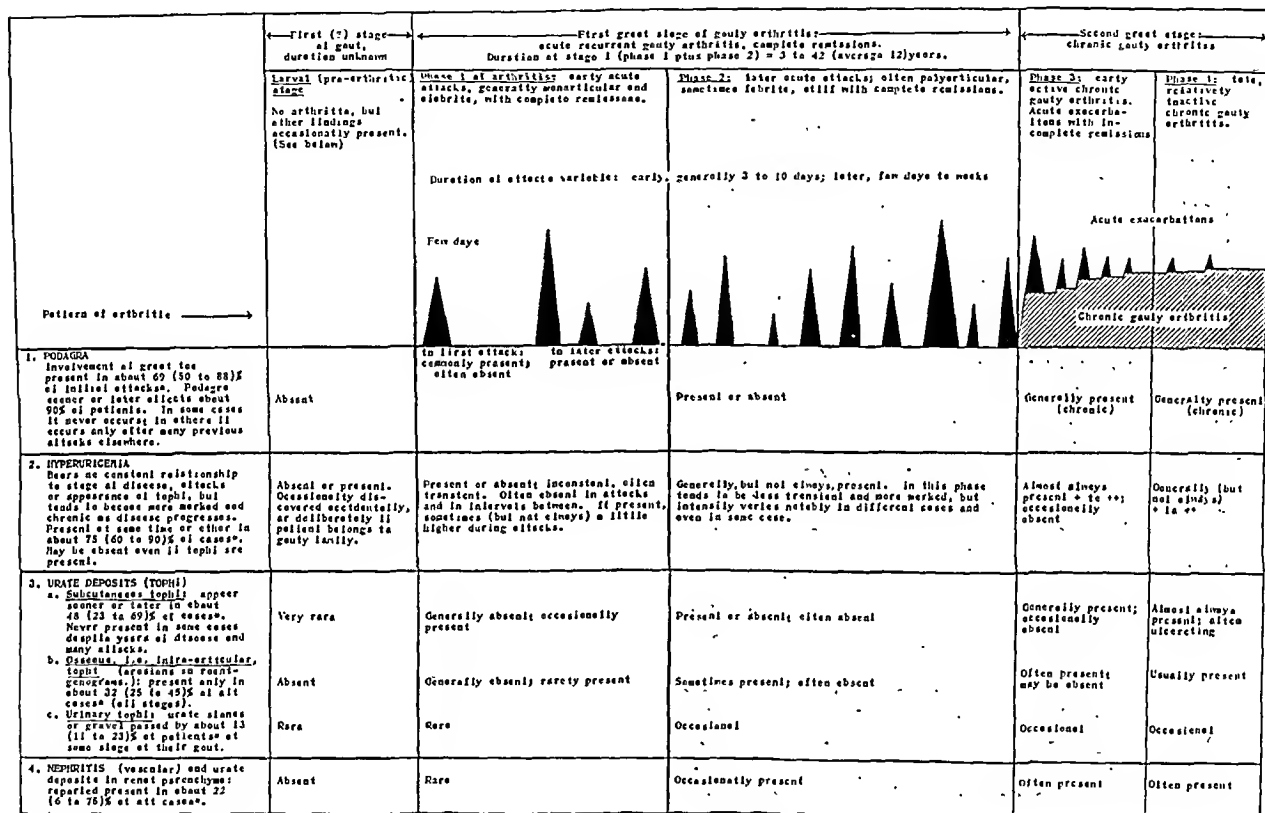

Physicians should not be content to postpone the diagnosis (and treatment) of gout until late in the disease when these "classic features" have become glaringly obvious. Without these features how can an early diagnosis be made? It can be made (1) during the first or any subsequent attack on the basis of certain features which are highly characteristic of the individual attacks or (2) after the second or later attack on the basis of the obviously developing characteristic pattern of gouty arthritis (fig. 2). This clinical pattern, which is made by acute recurring attacks and complete remissions, is so distinctive of gout as to be almost pathognomonic; it permits a diagnosis of presumptive or pretopaceous gout (in contrast to the diagnosis of tophaceous gout) with no little assurance, since it is not exactly mimicked by any of the other articular diseases which have recurrences and complete articular remissions; for example, rheumatic fever and intermittent hydrarthrosis.

Diagnostic Features of Individual Attacks.—When the patient is seen in the first or second attack with only a fragment of the clinical pattern in view, diagnosis is based on certain features, no one of which is diagnostic but a combination of which is almost pathognomonic for gout. Attacks which sometimes appear "spontaneously" commonly occur after some characteristic provocative, such as minor trauma or dietary indiscretion and less commonly after infection,

4. Hench, P. S., and Darnall, C. M.: A Clinic on Acute, Old-Fashioned Gout, with Special Reference to Its Inciting Factors, *M. Clin. North America* 16: 1371-1393 (May) 1933.

surgical procedures, certain medicines and psychic upsets. Unaware of their significance, patients rarely mention these provocatives; they must be sought.⁶ Attacks sometimes begin in the early morning hours but are usually noted when, on awakening, the patient puts the foot to the floor. In gout there is a gradient of articular vulnerability whereby the peripheral joints of the feet, ankles, hands and wrists are affected most often, the knees and elbows less often, the shoulders and hips rarely, and the spine very rarely if ever. Olecranon bursitis and achilles tendinitis often occur. When a great toe is affected, maximal tenderness is usually on its medial aspect, not on its top or bottom as in atrophic (chronic infectious, rheumatoid) arthritis. A gouty foot is more often warm and red or bluish

("exposition gout") or from long motoring (pedaling), or from excesses in golf or amateur laboring, for example, lawn mowing.⁴ Post-traumatic gouty arthritis can be differentiated from true traumatic arthritis thus: True traumatic arthritis begins immediately after trauma; the inflammatory reaction is proportional to the severity of trauma, is confined to the traumatized region and is not relieved by colchicine; the characteristics of gout (history, hyperuricemia, tophi) are absent. In post-traumatic gouty arthritis the inflammatory reaction is often delayed some hours after trauma, is out of proportion to the amount of trauma experienced, often progresses to other nontraumatized joints and is relieved by colchicine; some of the characteristic features of gout may also be present.

*Summarized from recent literature

Fig. 2.—The basic pattern of gout and gouty arthritis (untreated).

red than clammy, cold and bluish white as in atrophic arthritis. Shiny skin, some edema and later desquamation of the skin often are notable. Attacks of gouty arthritis usually develop more rapidly than attacks of any other acute arthritis; maximal disability may appear within twelve to thirty-six hours. Pain may be moderate but is usually marked and is often excruciating; it may or may not be worse at night. Recovery may be slow but is generally (spontaneously) rapid, occurring within a few days, and in the first stage of the disease it is complete.

Diagnostic Features Summarized Axiomatically.—My diagnostic criteria of gout and gouty arthritis are expressed in twenty-one points, as follows:

1. Suspect gout when acute arthritis suddenly develops after relatively trivial trauma, such as a walk of unaccustomed length, that from excessive sight seeing

2. Suspect gout when acute arthritis develops after dietary excesses of holidays, birthdays, lodge night, conventions and the like.⁴

3. Suspect gout when arthritis develops acutely within the first week after any surgical procedure; acute postoperative arthritis is usually gouty.⁶

4. Suspect as gout an acute arthritis appearing after the trauma, exposure and dietary excesses (venison, meat, alcohol) of a fishing or hunting trip⁴ (fig. 1).

5. Suspect as gouty an acute arthritis which recurs in the spring or fall. Attacks, however, may occur any time.

6. Suspect gout when acute arthritis begins between 2 and 7 a. m., but gouty arthritis may occur at any hour.

7. Suspect gout when acute arthritis occurs while a patient is being given liver extract for anemia, mersalyl

6. Hench, P. S.: A Clinic on Some Diseases of Joints: II. Acute Postoperative Arthritis: Its Identification; III. Acute Postoperative Gout: Its Treatment and Prevention, *M. Clin. North America* 10: 551-583 (Sept.) 1935.

(salyrgan) for dropsy,⁷ ergotamine tartrate (gynergen) for migraine, a ketogenic regimen, thiamine hydrochloride (vitamin B₁),⁸ dehydrocholic acid (decholin)⁹ or insulin (rarely).¹⁰ These are the medicinal provocatives of gout.

8. Suspect as gouty the acute arthritis of patients with leukemia or polycythemia or other dyscrasias involving destruction of blood and liberation of nucleoproteins.

9. Be cautious about making a diagnosis of gout in females; gout rarely affects females but when it does so it affects them in the classic manner. About 95 to 98 per cent of cases of provable gout occur among males.

10. Suspect as gouty any acute arthritis which suddenly and spontaneously affects a man more than 40 years of age; among such persons gouty arthritis is the commonest type of acute arthritis, but it may affect young persons of either sex.

11. Suspect gout when acute arthritis comes on and produces maximal disability with dramatic speed, within a few minutes or hours.

12. Suspect gout when the pain of an acute, but short lived, arthritis is unusually severe; "the worst ever."

13. Suspect gout when a great toe is acutely, not chronically, affected, and especially when the maximal tenderness is on its mesial aspect. Podagra, however, may occur late or never in a given case.

14. Suspect gout when an acutely affected foot is warm and red or bluish red rather than cold and bluish white as in atrophic arthritis and when edema and later desquamation of the skin are present.

15. When a patient presents himself, wearing a split shoe or a cut-out shoe, think of gout (fig. 1). Feet affected with atrophic arthritis usually are involved bilaterally and the swelling therein develops so gradually that the patient buys larger shoes. But in acute gouty arthritis the swelling progresses and regresses so rapidly that the patient handles the temporary articular emergency (so often unilateral) by splitting an old shoe.

16. In particular, suspect as gout any single attack of acute arthritis of short duration (from one to three weeks) which, especially considering its severity, disappears rather rapidly and completely. So complete are the remissions that "a person subject to gout has won the race at the Olympic games during the interval of the disease."¹¹

17. Consider any patient with chronic arthritis who has previously had (generally several) recurrent attacks of acute arthritis with complete remissions, to have gout until proved otherwise (fig. 2). Search for hyperuricemia and subcutaneous or osseous tophi, but if they are absent do not hesitate to make a diagnosis of "presumptive gout" at least to the extent of instituting a therapeutic test.

18. Since olecranon bursitis is several times commoner in gout than in any other disease, suspect gout in patients who have it or give a sought for history thereof.

19. When the shoulders, hips or spine are acutely or chronically affected, make a diagnosis of gout with great caution and only on the basis of unmistakable signs of gout and of gouty arthritis elsewhere. Such is the gradient of articular vulnerability in this disease that gouty arthritis affects the spine rarely if ever, the hips and shoulders rarely and generally only after previous attacks in more peripheral joints. Gout does not tend to produce a rheumatism of the torso.

20. Suspect gout in cases of acute or chronic arthritis in which there is a history or signs of renal colic (urate stones or gravel) or nephritis. Renal stones and nephritis affect about 10 per cent or more of gouty patients but rarely affect patients with atrophic, or hypertrophic (senescent, degenerative, osteo-) arthritis and then only coincidentally. It must be remembered that urate stones cast no roentgenographic shadows.

21. When periarticular or para-articular ulcers or fistulas are present, rule out gout. Ulcerating gouty tophi are now more common than ulcerating tuberculous fistulas of the joints.

Of all these points a characteristic history of the articular attacks is the most important for early and accurate diagnosis. When such a history is absent, therapeutic and provocative tests have indicated, in my experience, that gout is rarely if ever present, regardless of the presence of other features suggesting gout. Provocative tests performed by giving excessive quantities of purine, fats or both are only occasionally helpful in diagnosis. Much more reliable are therapeutic tests, for which colchicine in full doses is used alone or with other antigout measures.

TREATMENT

Prophylaxis.—Children and other relatives of gouty patients sometimes possess symptomless hyperuricemia.¹² Such hereditary candidates for gout should live moderately, avoid occupations permitting gastronomic overindulgence and avoid or undertake cautiously the various provocatives of acute gout.

Treatment of Acute Gouty Arthritis.—Patients who experience recognizable nonarticular prodromes (some note nausea, dyspepsia, polyuria or euphoria and a rayenous appetite) or warning articular twinges can sometimes abort the impending attack by taking a brisk cathartic and a few doses of colchicine (each dose $\frac{1}{400}$ grain, or 0.65 mg., every two to three hours). It is better to institute such a regimen needlessly for a false alarm than to permit an attack to become established. When the latter does happen, treatment includes the following measures:

Cathartic: A brisk cathartic, magnesium sulfate from $\frac{1}{2}$ to 1 ounce (15 to 30 Gm.), solution of magnesium citrate from 6 to 12 ounces (180 to 360 cc.) or sodium phosphate from 4 to 8 Gm., supposedly will promptly evacuate provocative toxins; its use is empiric but apparently helpful.

Rest: Affected parts should be rested completely, preferably in bed, and protected from bedclothes by a light wooden or metal cradle. Weight bearing and activity should be avoided until pain and tenderness disappear; otherwise an exacerbation may result.

Heat or Cold: Simple hot water compresses reapplied every one or two hours are generally effective and often

M.: The Uric Acid in the Serum of Gouty and of Non-Gouty Individuals: Its Determination by Folin's Recent Method and Its Significance in the Diagnosis of Gout, *Ann. Int. Med.* 11:1277-1295 (Jan.) 1938. Talbot, J. H.: Serum Urate in Relatives of Gouty Patients, *J. Clin. Investigation* 19:645-648 (July) 1940.

preferable to dry heat. Compresses of magnesium sulfate or lead lotion are prescribed by some physicians, lotions of aconite, belladonna and chloroform by others. Sometimes cold compresses give the most relief.

Colchicine: Colchicine tablets, each $\frac{1}{120}$ or $\frac{1}{100}$ grain (0.53 or 0.65 mg.), should be given: two tablets initially and one tablet every two or three hours (in severe cases even during the night) until pain is relieved or some gastrointestinal disturbance, such as nausea or diarrhea, appears. Having once learned his toxic or "diarrhea dose," a patient in subsequent attacks may (or may not) be able to obtain a satisfactory effect without the toxic effect by taking one or two less tablets in a course. Colchicine is more consistently effective than the wine or tincture of colchicum (dose from 15 to 30 minims or 1 to 2 cc. every two to four hours), which sometimes deteriorates. Gouty patients should carry a few colchicine tablets for prompt use when necessary.

Narcotics: Until pain is controlled by colchicine and compresses, a dose of two of codeine (from $\frac{1}{2}$ to 1 grain, or 0.032 to 0.065 Gm.) or morphine sulfate (from $\frac{1}{8}$ to $\frac{1}{4}$ grain, or 0.01 to 0.016 Gm.) may be required.

Cinchophen and Substitutes for Cinchophen: Attacks are better controlled when cinchophen or a substitute for it is used to supplement other measures, especially if hyperuricemia is present. Cinchophen should be given during attacks thus: $7\frac{1}{2}$ grains (0.5 Gm.) three or four times daily with the precautions noted later in this paper (alkali, carbohydrates, extra fluid).

Some physicians prefer to prescribe one of the following substitutes daily during the attack: neocinchophen from 5 to $7\frac{1}{2}$ grains (0.3 to 0.5 Gm.) three times a day; sodium salicylate 20 grains (1.3 Gm.) four times a day or acetylsalicylic acid 20 grains (1.3 Gm.) three or four times a day. I agree with those who have noted that in some cases these substitutes are not completely effective and inferior to cinchophen;¹³ but cinchophen or a substitute for cinchophen used without colchicine is also inadequate in some cases.¹⁴

Diet: The diet currently approved for acute gouty arthritis is free of purines and low in fats (the latter inhibits urate excretion), rich in carbohydrates, which increase urate excretion, and rich in purine-free proteins (milk, eggs, cheese). This diet minimizes the formation of exogenous urates and fosters elimination of endogenous urates. Its rationale may be questioned when it is realized that many patients during attacks excrete urates normally or even excessively. Future work must determine how necessary purine restrictions are during attacks, but then of all times patients are receptive to instruction in those dietary restrictions which the interval treatment of gout seems to require. Complete abstinence from alcohol is advisable.

Interval Treatment of Symptomless Gout and Control of Hyperuricemia.—Gout is not cured when the attack is over. Gout is a chronic disease for which treatment must be continued indefinitely in an attempt to prevent or postpone return of symptoms. Contrary to the belief of a few physicians that no regimen materially alters the "relentless progress of gout," most physicians believe that, by adhering faithfully to the interval treatment, the majority of patients can sharply modify the course of their disease, reduce the number and severity of attacks, prevent or reduce the likelihood of chronic gouty arthritis and avoid or postpone the late and some-

times fatal renal and cardiovascular complications. The faithful and successful adherence to such a regimen, however, requires, most of all, a high degree of self-discipline on the patient's part.

Purine Content of Certain Foods*

List 1. Foods which contain very large amounts (150 to 1,000 mg.) of purine bodies in 100 Gm.

Sweetbreads.....	825 mg.	Kidneys (beef).....	200 mg.
Anchovies.....	363 mg.	Brains.....	195 mg.
Sardines (in oil)...	295 mg.	Meat extracts.....	160-400 mg.
Liver (calf, beef)...	233 mg.	Gravies.....	Variable

List 2. Foods which contain a large amount (75 to 150 mg.) of purine bodies in 100 Gm.

Bacon, beef, calf tongue, carp, chicken soup, codfish, duck, goose, halibut, lentils, liver sausage, meat soups, partridge, perch, pheasant, pigeon, pike, plaice, pork, quail, rabbit, sheep, shellfish, squab, trout, turkey, veal, venison

List 3. Foods which contain a moderate amount (up to 75 mg.) of purine bodies in 100 Gm.

Asparagus, bluefish, bouillon, cauliflower, chicken, crab, eel, flounder, haddock, ham, herring, kidney beans, lima beans, lobster, mushrooms, mutton, navy beans, oatmeal, oysters, peas, salmon, shad, spinach, tripe, tuna fish, whitefish

Also whole grain bread and breadstuffs: graham bread, graham crackers, oatmeal crackers, rye bread, Rye Krisp, whole wheat bread, Zed

Also whole grain cereals: Bemax, bran, bran flakes, cracked wheat, Embo, graham porridge, Grape-nuts, Krumbles, malt breakfast food, Pep Bran Flakes, Pettijohns, Puffed Wheat, Ralston's, Sims, Shredded Wheat, Wheaties, Wheat oats, Wheatworth, Whole Wheat Krumbles

List 4. Foods which contain an insignificant amount of purine or no purine:

1. Beverages	7. Cheese of all kinds †
Carbonated	8. Eggs
Chocolate	9. Fats of all kinds (but eat in moderation)†
Cocoa	10. Fruits of all kinds
Coffee	11. Gelatin
Fruit juices	12. Milk
Postum	Buttermilk
Tea	Condensed milk
2. Butter †	Malted milk
3. Breads and breadstuffs (except whole grain under list 3)	13. Nuts of all kinds †
Benson's water crackers	Peanut butter †
Butter thins	14. Pies (except mince-meat)†
Corn bread	15. Shad roe
Corn sticks	16. Sugar and sweets
French bread	17. Vegetables
Gluten bread	Artichokes
Holland rusk	Beets
Soda crackers	Beet greens
Uneda biscuit	Broccoli
Winter rolls	Brussels sprouts
White bread	Cabbage
Zwieback	Carrots
4. Caviar	Celery
5. Cereals (except whole grain under list 3)	Corn
Breakfast brownies	Cucumber
Cornflakes	Dandelion greens
Cream of wheat	Eggplant
Farina	Endive
Grits	Kohlrabi
Hot toasties	Lettuces
Puffed rice	Okra
Rice flakes	Parasprouts
Rice krispies	Potato
White cornmeal	Sweet
Yellow cornmeal	White
6. Miscellaneous cereal products	Pumpkin
Arrowroot	Rutabagas
Hominy	Sauerkraut
Macaroni	String beans
Noodles	Summer squash
Sago	Swiss chard
Spaghetti	Tomato
Tapoca	Turnips
Vermicelli	18. Vegetable and cream soups (to be made with allowed vegetables and without meat stock)
	19. Vitamin concentrates
	Cod liver oil
	Halibut oil
	Yeast

* To calculate the purines or "purine bodies" in a given food the purine nitrogen is multiplied by 3; example, 200 mg. of purine nitrogen equals 600 mg. of purine bodies.

† These foods are high in fat.

Hyperuricemia and urate deposits are the result, not the cause, of gout and they bear an uncertain, perhaps even no, relationship to the acute articular attacks, but they do bear an important causal relationship to the production of chronic gouty arthritis, which represents

13. Kersley.¹³ Lockie.¹⁴

14. Lockie, L. M.: A Discussion of a Therapeutic Test and Provocative Test in Gouty Arthritis, *Ann. Int. Med.* 13: 755-760 (Nov.) 1939.

a foreign body reaction to the urate deposits. Hence it is necessary to combat chronic hyperuricemia (1) by dietary restrictions and (2) by the intermittent use of urate eliminants; that is, urate diuretics.

Dietary Restrictions: Each patient must be treated individually as the stage and severity of his disease and his temperament dictate. In general the diet should be free of purines on two, not necessarily consecutive, days and low in purines five days a week. Normal diets contain from 600 to 1,000 mg. of purines (that is, purine bodies) daily; a low purine diet contains from 100 to 150 mg. and can be attained roughly by allowing one food from list 2 in the accompanying table one day a week and one from list 3 four days a week, besides whatever foods are desired from list 4. Obesity should be avoided, but normal weight should be maintained. Two days each week the selections should be only from list 4 (foods free of purines). The foods in list 1 (foods rich in purines) should always be avoided entirely. It is customary to advise the avoidance also of spices, condiments and rich or indigestible foods and sauces in an attempt to prevent those gastrointestinal or particularly hepatic disturbances which may somehow initiate acute attacks. The low purine and purine-free diets just outlined may be deficient in protein, iron and vitamin B₁; generally the diet must be reinforced by administration of iron (ferrous sulfate 5 grains, or 0.3 Gm., daily) and an approved preparation of the vitamin B complex (at least 200 international units of thiamine hydrochloride and 200 Sherman-Bourquin units of riboflavin daily).

Coffee and tea are permissible, being methylated purines which do not form uric acid. Some veterans of gout insist that they can consistently tolerate certain alcoholic drinks but not others; since they cannot agree on which are harmless, the gouty novice should avoid all alcohol unless prepared to pay the price of personal experimentation.

It must be emphasized that gout may affect vegetarians and teetotalers. Purines and alcohol do not cause the disease gout any more than sugar causes diabetes. Once a person has diabetes (insulin deficiency) excessive intake of sugar may provoke symptoms. So, too, once a man has gout, and only then, will excessive intake of alcohol and purines provoke the quiescent gout into symptomatic activity and cause acute gouty arthritis (fig. 1), but so also high fat and ketogenic diets may provoke acute articular attacks.

Physicians who espouse the allergic theory consider the avoidance of purines less important than the avoidance of foods to which, regardless of their purine content, patients may be individually allergic as suggested by cutaneous tests or by their apparent provocative effect. For example, asparagus, not especially rich in purines, is said to provoke attacks in some persons. The rationale of such special restrictions is not yet clear, but physicians should cater to established idiosyncrasies.

Urate Eliminants (urate diuretics): For the many patients who cannot control symptoms and hyperuricemia by diet alone, the additional use of some urate eliminant is required: acetylsalicylic acid, sodium salicylate, sodium salicylate "augmented" by aminoacetic acid, neocinchophen or cinchophen. I believe that cinchophen is the most effective and that there is no exact substitute for it, but because of its occasional toxicity a substitute should be tried first. Salicylates augment urate excretion but generally have been considered inferior to cinchophen and ineffective except as mild analgesics

unless large irritating doses are used. But Jennings¹⁵ recently concluded that salicylates are as effective as cinchophen in controlling pain and hyperuricemia. He prescribed sodium salicylate 80 grains (5.3 Gm.) daily and sodium bicarbonate from 120 to 150 grains (8 to 10 Gm.) daily for three or four consecutive days each week to be continued indefinitely as interval therapy. Others prescribe acetylsalicylic acid from 60 to 80 grains (4 to 5.3 Gm.) daily, four consecutive days each week. Another scheme, based on Quick's report¹⁶ that aminoacetic acid (glycine) augments the uricosuric action of salicylates is this: sodium salicylate 60 grains (4 Gm.) and aminoacetic acid 150 grains (10 Gm.) daily three consecutive days a week.

If symptoms of the disease and the hyperuricemia are not satisfactorily controlled by diets and these drugs, I believe that the intermittent use of cinchophen is justified except for those patients who have hepatic dysfunction or an idiosyncrasy to cinchophen or who are unwilling to accept the slight risk. At the Mayo Clinic we use the plan of Graham:¹⁷ cinchophen 7½ grains (0.5 Gm.) three times daily for three consecutive days each week. The drug is continued thus indefinitely, but occasionally the dose is reduced or the drug withheld temporarily as control of gouty symptoms and of hyperuricemia permit. If the blood uric acid becomes normal or nearly so, the drug may be temporarily omitted or given for a while only one or two days a week in the usual doses or in smaller doses three days a week. Some physicians "go half way" in the matter of cinchophen and regard the use of neocinchophen from 5 to 7½ grains (0.3 to 0.5 Gm.) three times a day, two or three days every week or two, as a satisfactory compromise, but no final opinion can be given as to whether this is safer than cinchophen.

"Precautions" Against Cinchophen Toxicity: Whenever cinchophen is given, certain precautions must be taken: the ingestion of about 2 liters of fluid daily and of liberal amounts of carbohydrates. Cinchophen carries a definite risk, which some physicians never condone but which most students of gout¹⁸ consider justifiable if gout is uncontrolled otherwise. Serious toxic reactions from cinchophen are, after all, rather rare, especially in gouty patients. The chances of serious or fatal intoxication from cinchophen in gouty patients is believed to be only a small fraction of 1 per cent. This risk must be contrasted with that of the disease itself: in from 10 to 20 or more per cent of cases gouty nephritis develops which is sometimes fatal,¹⁹ and the incidence of renal colics from urate gravel and of cardiovascular lesions is notable. Since the disease thus carries a much greater risk than its treatment by cinchophen, it seems justifiable to assume the small risk of the latter, when necessary, to try if possible to prevent the articular, renal and vascular consequences of gout. Patients should be told of the risk of toxic reactions

from cinchophen and instructed to report such unusual symptoms as anorexia, dyspepsia, nausea, loss of weight, pruritus or jaundice, to stop taking the drug at once, and to report for special therapy (carbohydrates intravenously, high carbohydrate diet, vitamin supplements and so on).

Alkalis: During the administration of urate diuretics, patients should take enough alkali to insure constant urinary alkalinity in order to prevent renal colic from the precipitation of urate gravel or stones in acid urine. They can learn to test the urine with litmus paper to determine the amount of alkali individually required; this varies somewhat, but potassium citrate from 15 to 30 grains (1 to 2 Gm.) three times a day or sodium bicarbonate from 30 to 60 grains (2 to 4 Gm.) three times a day generally suffices. These amounts of sodium bicarbonate occasionally produce gastrointestinal disturbances which may be erroneously ascribed to cinchophen; if these occur, an alternate method of urinary alkalization is necessary.

Other Measures: Contrary to general opinion, a few physicians consider colchicine to be a preventive of acute attacks and prescribe $\frac{1}{120}$ grain (0.53 mg.) three times a day for two or three days each week or in one week of each month. With similar intent others²⁰ gave from 330 to 3,300 international units of vitamin B₁ (thiamine hydrochloride) daily continuously even though initial doses commonly provoked acute attacks. The value of such therapy is not established. Of more certain value is the constant avoidance of the several known provocatives of gout, not only the gastronomic but also the traumatic, medicinal, psychic, surgical and infectious provocatives. Acute postoperative gouty arthritis generally can be prevented by the use of a high carbohydrate, purine-free diet and cinchophen (or substitute) for five days before and also for five days after operation.⁶ Improved control of gouty patients after removal of obviously infected foci has been reported.

There is disagreement as to the value of physical therapy (aside from simple heat or cold) during acute gouty arthritis and the intervals thereafter. Most physicians regard massage and exercises to be absolutely contraindicated at any stage of the attacks but helpful as a feature of interval therapy.²¹ But "cure crises" are often precipitated by such therapy; hence I do not recommend it.

Treatment of Chronic Gouty Arthritis.—Chronic gouty arthritis may be prevented by the regimen outlined; if not, various types of physical therapy are required, especially heat to foster resorption of urates. Fever therapy or typhoid vaccine reactions have been used occasionally. Massage, exercise and spa therapy must be used cautiously lest an exacerbation be evoked.

Treatment of Tophaceous Ulcers.—Large tophi on the hands and feet may ulcerate (in later phases of gouty arthritis) and partially heal, only to break down intermittently, sometimes discharging urates for months; occasionally they become infected, necessitating consideration of amputation. This eventuality can be avoided by the early excision of tophi in which ulceration is present or impending. When débridement is done thoroughly, prompt healing occurs. Unless the tophus is small it is best, before removal, to institute the regimen for the prevention of postoperative gouty arthritis.

Treatment of Renal and Other Complications.—The treatment of gouty nephritis involves a generous intake of fluids (2 or 3 liters daily), restrictions of protein as necessary, and continued efforts to combat the underlying gout and its hyperuricemia. Prevention of gouty calculi by urinary alkalization has been mentioned already. Nonopaque to roentgen rays, such calculi are usually small and pass without surgical intervention. There is no specific treatment for the cardiovascular complications of gout.

Prognosis: Results of Treatment.—Prognosis is best for those whose symptoms develop late, poorest for those with symptoms early in life, especially in their teens. Some patients have mild gout for years, only symptomatic on rare occasions after special stress such as a surgical procedure. Despite instructions, patients may fail to control their gout because of half hearted application of the regimen (the most common reason), because their gout is uncontrollable by diet alone (the next most common reason), because of irritating occupational or other trauma, the unwitting use of some medicinal provocative, or because of the presence of some chronic aggravating infection, blood dyscrasia, such as polycythemia or leukemia, chronic plumbism or coincidental metabolic fault (unsuspected mild diabetes or thyroid dysfunction). The correction of these factors usually results in improved control of the disease. Cases of truly uncontrollable or irreversible gout are not as common as some physicians suppose.

THE CLINICAL SYNDROME ASSOCIATED WITH INTERCAPILLARY GLOMERULOSCLEROSIS

WILLIAM B. PORTER, M.D.

AND

HARRY WALKER, M.D.

RICHMOND, VA.

In 1936 Kimmelstiel and Wilson¹ reported on a group of 8 patients showing a striking hyaline thickening of the intercapillary connective tissue, most clearly seen at the hilus of the glomeruli. They felt that the change was degenerative and suggested that arteriosclerosis and diabetes mellitus played a part in its causation. The most significant clinical features of their cases were diabetes mellitus, usually of long duration, edema of the nephrotic type, gross albuminuria and varying degrees of hypertension.

This report is concerned with an analysis of the clinical and laboratory features of 8 patients who had mild diabetes mellitus, 6 of these showing at autopsy the intercapillary lesions in the glomeruli as described by Kimmelstiel and Wilson. Permission for autopsy on the other 2 was not obtained but we feel that their clinical course justifies the conclusion that they too would have shown these changes in the kidney.

REPORT OF CASES

CASE 1.—History.—J. W., a Negro aged 59, admitted to the medical service Oct. 27, 1937, complained chiefly of pain and tenderness of the left foot of three weeks' duration. One week previously his physician examined him and discovered

Dr. Paul Kimmelstiel analyzed the pathologic data.

From the Department of Internal Medicine, Medical College of Virginia.

Read before the Section on Practice of Medicine at the Ninety-First Annual Session of the American Medical Association, New York, June 13, 1940.

glycosuria. Polydipsia had been present for at least two years, swelling of the legs for three months and impairment of vision for a year or longer. He had been a bed patient since the onset of the involvement of the left foot.

The patient was well developed and well nourished. When he was examined he was lying flat in bed; there was no dyspnea and no distress. The temperature was 103.8 F., the pulse rate 110 and the respiratory rate 22 a minute. Examination of the optic fundi showed slight blurring of the nasal side of the disk and old exudates in both fundi, with marked arteriosclerosis of the retinal arteries. The heart was apparently normal in size and shape and there were no murmurs. There was no venous stasis. The blood pressure was 160-170 systolic and 90-105 diastolic. There were signs of patchy bronchopneumonia in both lungs. There was marked generalized arteriosclerosis, and no pulse was recorded in the posterior tibial or dorsalis pedis of either lower extremity. Ischemic gangrene of the anterior third of the left foot was present. There was moderate edema in the lumbosacral area.

Laboratory examination revealed the hemoglobin content to be 80 per cent, the red blood cell count 3,750,000 and the white blood cell count 22,750-34,240 with polymorphonuclear neutrophils 85 per cent-92 per cent. Urinalysis showed: specific gravity 1.020, albumin 3+, sugar 2+, acetone 0, and sediment containing a few hyaline and granular casts. Blood sugar was 206-296 mg. and nonprotein nitrogen 38-44 mg. per hundred cubic centimeters; total protein 4.8 Gm., albumin 2.6 Gm. and globulin 2.2 Gm. per hundred cubic centimeters, and cholesterol 320 mg. per hundred cubic centimeters.

During his stay in the hospital the gangrene of the left foot progressed and fever, varying from 102 to 104.4 F., continued. On the seventh hospital day the left leg was amputated below the knee. The bronchopneumonia became more widespread and the patient died on the fifteenth hospital day.

Necropsy.—There were marked generalized arteriosclerosis and bilateral bronchopneumonia. The heart weighed 330 Gm. Microscopically the kidneys showed intercapillary glomerulosclerosis of moderate degree but far in excess of mere aging processes. There was only a moderate degree of diffuse arteriosclerosis and no tubular dilatation. There was considerable edema of the interstitium between the tubules, particularly in the cortex and scattered foci of polymorphonuclear leukocytes, lymphocytes and a few monocytes and plasma cells. The microscopic changes were those of acute serous interstitial nephritis and moderate intercapillary glomerulosclerosis.

CASE 2.—History.—J. K., a white man aged 62, seen in the outpatient department Oct. 7, 1935, complained chiefly of breathlessness with effort and recurring episodes of nocturnal dyspnea accompanied by cough.

Examination of the optic fundi revealed arteriosclerosis 2+ and no hemorrhages, exudates or edema of the disk. There was moderate cardiac hypertrophy; the second pulmonic sound was decidedly accentuated. Medium moist rales were heard at the lung bases. The blood pressure was 208 systolic and 124 diastolic; the pulse rate was 96; there was sinus rhythm. There was no dependent edema.

On laboratory examination the urine had a specific gravity of 1.025, albumin 2+ and sediment containing occasional hyaline casts. A blood count was normal and the Wassermann reaction was negative. Blood sugar was 154 mg. and nonprotein nitrogen 43 mg. per hundred cubic centimeters.

The patient was referred to the hospital for treatment and was discharged October 21. The diagnosis was hypertension, coronary insufficiency, cardiac hypertrophy, left ventricular failure and mild diabetes mellitus.

The patient was readmitted March 7, 1936, the chief complaint being breathlessness and recurring attacks of severe pain in the epigastrium radiating around the right costal margin.

The blood pressure was 230 systolic and 120 diastolic. There was tenderness over the gallbladder area, but otherwise no material change was found.

Urinalysis showed: specific gravity 1.024, albumin 2+, sugar 0 and sediment 0. Blood sugar was 157-224 mg. and nonprotein nitrogen 43 mg. per hundred cubic centimeters.

An added diagnosis of cholelithiasis was made.

The patient was admitted for the third time on November 3 with the chief complaint of pain in the upper right quadrant of three days' duration. The diagnosis was gallstone colic.

He was admitted for the fourth and final time on Feb. 3, 1937 with the chief complaint of orthopnea and progressive edema of the lower extremities.

When examined the patient was dyspneic and was propped up in bed. The heart was greatly enlarged. The blood pressure was 170-190 systolic and 118-120 diastolic. The pulse rate was 90-110 a minute; there was sinus rhythm. General venous hypertension was present. Postural edema extended up to the umbilicus. There were bilateral pleural effusion and moderate ascites.

On laboratory examination the urine showed a specific gravity of 1.030, albumin 3+ and sugar 0 and sediment containing a few hyaline and granular casts. Blood sugar was 162 mg., nonprotein nitrogen 55 mg. per hundred cubic centimeters; total protein 4.4 Gm., albumin 2.1 Gm. and globulin 2.3 Gm. per hundred cubic centimeters, and cholesterol 152 mg. per hundred cubic centimeters.

The patient became progressively worse and died on the tenth hospital day.

Necropsy.—The condition shown at necropsy was generalized arteriosclerosis; pronounced coronary sclerosis, cardiac hypertrophy (weight 700 Gm.); chronic passive congestion and cardiac cirrhosis of the liver. Microscopically the kidneys showed severe arteriosclerosis and arteriolar sclerosis and intercapillary glomerulosclerosis of a moderate degree. The tubules showed vicarious hyperplasia and hypertrophy.

CASE 3.—History.—M. T., a white woman aged 41, was admitted to the surgical service April 25, 1937 and died April 26. Her chief complaint was pain in the right lower quadrant, which was followed by generalized abdominal pain and tenderness. The illness was of thirty-two hours' duration. There was a history of polyuria and polydipsia for "many years," but no diagnosis of diabetes had been made.

On examination the patient was extremely ill. The temperature was 103.4 F., the pulse rate 120-140 and the respiratory rate 25-30 a minute. The heart and lungs were essentially normal; the arteries showed moderate arteriosclerosis. The blood pressure was 100-120 systolic and 65-75 diastolic. The phenomena of generalized peritonitis were evident.

Urinalysis showed a specific gravity of 1.032, albumin 4+, sugar 2+ and sediment 0. A blood count showed hemoglobin 100 per cent, red cells 5,200,000 and white cells 7,350, with a differential of 92 per cent polymorphonuclear neutrophils. The blood sugar was 400 mg. and nonprotein nitrogen 54 mg. per hundred cubic centimeters.

The patient died fourteen hours after admission to the hospital.

Necropsy.—This revealed generalized fibropurulent peritonitis following a ruptured gangrenous appendix. The heart weighed 350 Gm. The kidneys showed a moderate degree of intercapillary sclerosis involving all the glomeruli. The medium sized arteries showed only a slight degree of sclerosis, but there was a severe and diffuse arteriolar sclerosis. The tubules showed acute dilatation and there was some interstitial serous nephritis.

CASE 4.—History.—E. Mc., a Negro woman aged 55, was admitted to the medical service on Sept. 23, 1936 and died October 21. Her chief complaint was diarrhea with swelling of the feet, legs and abdomen. The swelling began in her feet in March 1936. This progressively increased until it became generalized, including the face. Diarrhea began three weeks before her admission to the hospital. The only significant statements suggesting diabetes were an excessive appetite with loss of weight, polyuria and polydipsia. Ten years previously, at a time when she felt well, she had expectorated blood on one occasion. There had been intermittent vaginal bleeding for three years and bleeding hemorrhoids for ten or more years.

Physical examination revealed generalized edema including the face, ascites and bilateral pleural effusion. The heart was normal. The blood pressure was 160-180 systolic and 80-90 diastolic. The peripheral vessels showed arteriosclerosis and atherosclerosis; the venous pressure was normal. The optic fundi showed arteriosclerosis 1+ and no edema, hemorrhages or exudates.

Urinalysis showed: specific gravity 1.016-1.018, albumin 3 + - 4 +, sugar 0, and sediment containing occasional hyaline and granular casts. A blood count showed hemoglobin content 48 per cent, red cells 2,520,000, and white cells 5,600 with a normal differential count. The hematologist who was consulted stated that the picture presented by the blood studies was that of chronic blood loss. The blood sugar was 196-260 mg., nonprotein nitrogen 30-53 mg., and cholesterol 224 mg. per hundred cubic centimeters; total protein 4.9 Gm., albumin 2.1 Gm. and globulin 2.8 Gm. per hundred cubic centimeters.

Necropsy.—The heart weighed 250 Gm. Submucous uterine fibroids were present. Microscopically the kidneys showed severe and diffuse arteriosclerosis and arteriolar sclerosis. The glomeruli showed advanced intercapillary sclerosis with occasional degenerative glomerulitis and numerous adhesions with extensive changes in the capsules. The tubules showed severe tubular dilatation and extensive metallaxis.

CASE 5.—History.—H. C., a white man aged 57, was admitted to the medical service on Sept. 12, 1936 and died September 13. He was admitted because of unconsciousness which developed suddenly and had become increasingly more complete. A history of diabetes "for many years" was obtained from the family.

When examined the patient was completely unconscious, and there was a flaccid paralysis of the left arm and leg. The optic fundi showed arteriosclerosis 2+ of the retinal vessels and many fresh hemorrhages, but there was no exudate or edema of the disk. The heart was moderately enlarged to the left, with a rate of 102. The peripheral arterics showed a moderate degree of arteriosclerosis. The blood pressure was 200 systolic and 104 diastolic. There was pitting edema of the legs extending to the thighs.

Urinalysis showed: specific gravity 1.025, albumin 4 +, sugar 1 +, sediment 0. The blood sugar was 320 mg., nonprotein nitrogen 46 mg. per hundred cubic centimeters; total protein 4.6 Gm., albumin 2.2 Gm. and globulin 2.4 Gm. per hundred cubic centimeters.

Death occurred a few hours after admission to the hospital, probably the result of a cerebral hemorrhage.

Necropsy.—This was confined to the left kidney. There was advanced intercapillary glomerulosclerosis with obvious deposition of hyaline and fat in the parietal capsule. There was extensive sclerosis of the arteries and arterioles. The tubules showed vicarious hyperplasia and hypertrophy. There were extensive metallaxis and scarring of the kidney tissue.

CASE 6.—History.—H. S., a Negro aged 52, admitted to the medical service July 31, 1939 and discharged August 17, complained chiefly of swelling of the legs and abdomen of three months' duration and mild breathlessness with effort. The patient stated that sugar had been found in his urine three years previously but that he had not followed the treatment prescribed.

The patient was moderately dyspncic, with extensive edema of the legs and sacral area, together with a moderate amount of ascites and bilateral pleural effusions. The optic fundi showed a moderate degree of sclerosis of the retinal vessels but no exudates or hemorrhage. The heart was enlarged, with a cardiothoracic ratio of 57 per cent. An electrocardiogram showed T₁ and T₂ isoelectric, with left axis deviation. The blood pressure was 175-185 systolic and 100-110 diastolic, pulse rate 88-96 a minute. There was moderate venous hypertension. The liver was 4 cm. below the costal margin; ascites was moderate.

Urinalysis showed: specific gravity 1.020-1.022, albumin 3 +, sugar 0-1 +, sediment 0. A blood count showed hemoglobin content 84 per cent, red cells 4,200,000; the leukocyte and differential counts were normal. The blood sugar was 192-246 mg., nonprotein nitrogen 36 mg., cholesterol 214 mg., and total protein 4.3 Gm., albumin 2.1 Gm. and globulin 2.2 Gm. per hundred cubic centimeters.

The clinical diagnosis was (1) cardiac hypertrophy and dilatation, (2) coronary insufficiency, (3) generalized arteriosclerosis, (4) mild congestive heart failure, (5) mild diabetes mellitus and (6) intercapillary glomerulosclerosis.

The patient showed satisfactory improvement after institution of a salt-poor diabetic diet, bed rest and mercury diuretics. He was discharged to the cardiac and diabetic clinics.

He was readmitted September 23. During his second hospital admission generalized edema, ascites and recurring pleural effusions were the most prominent clinical symptoms. Heart failure of the congestive type was never conspicuous, yet it existed to a mild degree. The blood pressure ranged from 140-160 systolic and 90-110 diastolic.

Urinalysis showed: specific gravity 1.012-1.018, albumin 4 +, sugar 0-1 +, sediment 0. Blood counts showed: hemoglobin content 80-85 per cent, red cells 4,100,000-4,300,000, with normal leukocyte and differential counts. The blood sugar was 150-220 mg., nonprotein nitrogen 34-48 mg., cholesterol 270-296 mg. per hundred cubic centimeters; total protein 4.5-5.1 Gm., albumin 2.2-2.5 Gm. and globulin 2.3-2.6 Gm. per hundred cubic centimeters.

The hospital course was characterized by unsustained improvement following administration of digitalis and diuretics, frequent thoracentesis and controlled diet. Death resulted from bronchopneumonia on December 9.

Necropsy.—The heart weighed 500 Gm. There was severe coronary arteriosclerosis. The lungs showed bronchopneumonia, bilateral, involving the lower lobes. Microscopically the kidney

Basement membrane stain. Thickened and hyalinized intercapillary connective tissue more pronounced, though of the same type as seen in the aging process of glomerulus. The capillary loops, endothelial and epithelial cells are normal. (Case of diabetes in middle aged person.)

showed severe arteriosclerosis, arteriolar sclerosis and extensive intercapillary sclerosis involving practically all of the glomeruli. There was vicarious hyperplasia and hypertrophy with deposition of fat and some hyaline droplets, degeneration of the tubules and a moderate degree of metallaxis.

CASE 7.—A. C., a white woman aged 67, admitted to the outpatient department in January 1935, complained chiefly of loss of 50 ± pounds (23 Kg.), breathlessness with effort, moderate edema of the ankles and polyuria. Examination revealed hypertension; the blood pressure was 210 systolic and 120 diastolic; there were general arteriosclerosis and probably cardiac enlargement but no phenomena of heart failure. Urinalysis showed albumin 2 + and sugar 3 +. The blood sugar was 280 mg. per hundred cubic centimeters. She was followed as an ambulatory patient in the diabetes clinic until Dec. 4, 1936.

She was first admitted to the hospital in the medical service on Jan. 5, 1938, and from this date until she left the city in December 1939 she was admitted eight times, remaining in the hospital on an average of eleven days.

The chief complaints on each admission were essentially the same, yet there was some variability in their severity. Breathlessness with effort was consistently present, but with

each admission edema was a prominent complaint, and on four occasions the edema was extensive and complicated by hydrothorax and ascites. The optic fundi showed arteriosclerosis 1+, without exudates or hemorrhages. The heart was moderately enlarged with a cardiothoracic ratio of 54 per cent. An electrocardiogram showed left axis deviation and moderately inverted T₁. The blood pressure was 165-190 systolic and 95-110 diastolic. The venous pressure was 110-120 mm. of water.

Urinalysis showed specific gravity 1.014-1.022, albumin 2+4+, sugar 0-2+, sediment 0. Blood counts showed: hemo-

globin content 75-85 per cent, red cells 3,400,000-4,100,000 and white cells 7,800-9,600, with a normal differential count. The blood sugar was 140-310 mg., nonprotein nitrogen 27-48 mg., and cholesterol 186-264 mg. per hundred cubic centimeters and total protein 4.4-5.1 Gm., albumin 2.4-2.6 Gm. and globulin 1.7-2.6 Gm. per hundred cubic centimeters.

The patient was consistently partially relieved of the edema by mercury diuretics in conjunction with ammonium chloride. The diabetes was moderately controlled with diet. The impression at the time of the last hospital admission was that her life expectancy was short and that death would result from cardiac and renal failure.

The clinical diagnosis was (1) hypertension, arteriosclerosis, cardiac hypertrophy, myocardial fibrosis, coronary artery sclerosis; (2) diabetes mellitus, mild; (3) nephrosclerosis with intercapillary glomerulosclerosis, severe; (4) nephrotic syndrome; (5) heart failure, congestive type, mild.

CASE 8.—C. W., a white woman aged 39 at the time of her death on Feb. 1, 1938, was first admitted to the medical service April 4, 1929 with a diagnosis of pyogenic infection of the right thumb and diabetes. The blood pressure was 100 systolic and 68 diastolic. Urinalysis showed specific gravity 1.022, albumin 0, sugar 3+. The nonprotein nitrogen was 26 mg. and the blood sugar 344 mg. per hundred cubic centimeters.

From 1929 to 1932 she was readmitted for various types of cutaneous infection, but nothing specific was noted, the diabetic state being partially controlled with diet and insulin.

She was readmitted to the hospital on April 14, 1932 because of pains in the lower extremities and edema of the ankles and eyelids. Examination showed edema of the eyelids, normal fundi, subnormal blood pressure, 98 systolic and 65 diastolic, slight edema of the ankles with absence of pulsation in the posterior tibial and dorsalis pedis arteries, diminished deep reflexes of the knee and achilles tendon.

The electrocardiogram was normal. The basal metabolic rate was +2 per cent. Urinalysis showed specific gravity 1.026, albumin 2+, sugar 3+, sediment 0. The blood count was normal. The blood sugar was 148-344 mg., nonprotein nitrogen 27-42 mg., cholesterol 276 mg. per hundred cubic centimeters; total protein 5 Gm., albumin 3.3 Gm., globulin 1.7 Gm. per hundred cubic centimeters. She was discharged to the diabetic clinic for treatment after eleven days of hospital care.

She was readmitted to the hospital on May 13, 1937 because of progressively increasing edema of the legs and abdomen, weakness, pain in the feet and slight breathlessness with effort, which developed after the edema extended to the abdomen. Physical examination showed edema of the lower extremities with a moderate amount of ascitic fluid, a blood pressure of 160 systolic and 80 diastolic, and generalized arteriosclerosis with

absence of pulsation in the posterior tibial and dorsalis pedis arteries. The optic fundi showed arteriosclerosis of the retinal vessels 1+ and an occasional flame hemorrhage; there was no edema of the disk.

Urinalysis showed specific gravity 1.016, albumin 3+, sugar 0 and sediment 0. The hemoglobin content was 78 per cent and red blood cells numbered 3,740,000. Blood sugar was 137-220 mg., nonprotein nitrogen 35-38 mg. and cholesterol 412 mg. per hundred cubic centimeters. The patient showed some improvement on a diabetic regimen with insulin, bed rest and mercury diuretics. She was discharged to the diabetes clinic.

She was readmitted on October 16 because of generalized edema and breathlessness. Physical examination showed generalized extensive edema, ascites and pleural effusion on the right side. The optic fundi showed no edema of the nerve head; there were superficial and deep hemorrhages and many cotton wool exudates; arteriosclerosis was 2+. There was generalized arteriosclerosis. A teleroentgenogram revealed a cardiothoracic ratio of 51 per cent; the blood pressure was 170 systolic and 100 diastolic. The electrocardiogram was normal. There were no evident signs of congestive heart failure.

Urinalysis showed specific gravity 1.011-1.020, albumin 4+, sugar 0-1+ and sediment 0. A blood count showed hemoglobin content 70 per cent, red cells 3,620,000 and white cells 7,400, with a normal differential count. Blood sugar was 150-186 mg., nonprotein nitrogen 40-52 mg. and cholesterol 160-204 mg. per hundred cubic centimeters and total proteins 4.2-4.4 Gm., albumin 2.6-2.8 Gm. and globulin 1.6-1.8 Gm. per hundred cubic centimeters. The congo red test showed retention of 66 per cent of the dye for sixty minutes. The phenolsulfonphthalein test resulted in 24 per cent excretion for two hours.

There was a moderate reduction in the edema following the use of mercury diuretics and the restriction of salt and water. The right pleural cavity was aspirated three times; the total fluid removed was 2,650 cc., which had a specific gravity of 1.012-1.014. The patient was discharged from the hospital on Jan. 29, 1938 and died at her home February 1.

There was no autopsy. The clinical diagnosis was (1) diabetes mellitus, (2) generalized arteriosclerosis, (3) severe intercapillary glomerulosclerosis, (4) nephrotic syndrome and (5) renal insufficiency (table 1).

COMMENT

In the choice of cases for this study we have selected patients who showed both advanced and mild degrees of hyaline thickening of the intercapillary tissue of the glomeruli. Also included are two patients who were

followed clinically from an early stage to the time the syndrome became fully developed. An analysis of these cases shows that the well developed syndrome probably represents the end stage of a progressive process, the latter phase being preceded by certain suggestive clinical changes and laboratory studies, one of these being the appearance of albuminuria during the course of mild diabetes in a patient past the fourth decade. A review of case 8 illustrates the most probable course of events and its relation to the progress of the renal lesions. The diagnosis of diabetes mellitus was made in 1929. Albuminuria, mild edema, arteriosclerosis and

mild hypoproteinemia were first recognized three years later in 1932. At this time the blood pressure was 98 systolic and 65 diastolic. Five years later, in 1937, the edema was excessive, the blood pressure 160 systolic and 80 diastolic, arteriosclerosis more advanced, albuminuria 3+ and total proteins of 4.1 Gm. per hundred cubic centimeters. The patient died in 1938 after a prolonged illness characterized by generalized edema of the nephrotic type, and hypertension (160-180 systolic and 80-95 diastolic). The immediate cause of death is not known, for the patient died at home; however, renal insufficiency was evident when the patient left the hospital.

In this series of cases, both from the clinical standpoint and from the autopsy material studied, one is impressed not only by the renal lesions but also by the arteriosclerosis throughout the vascular tree, particularly in the coronary, mesentery and the arteries of the lower extremities. Hypertension was found at some time during the period of observation in all except case 3; yet in only three cases did the pressure exceed 200 mm. of mercury systolic at any time during observation. The heart weights (table 2) were in three instances within the range of normal from 250 to 350 Gm., and in case 8 there was no significant cardiac enlargement. These facts suggest that the associated hypertension was of a mild type or of short duration.

Newburger and Peters² in a recent report state that the pathogenesis of this condition may "depend on severe and extensive arterial and arteriolar degeneration associated with and perhaps resulting in diabetes mellitus, hypertension and renal damage." They also emphasize the fact that the cases studied by them presented many of the features of malignant hypertension. This may be true at times, but from a study of our material we cannot conclude that features of malignant hypertension are an essential aspect of the clinical syndrome of intercapillary glomerulosclerosis. In fact, none of our patients, with the possible exception of the first one, showed the presence of the optic fundus changes characteristic of malignant hypertension, nor did the kidneys in any case show the arteriolar changes characteristic of malignant nephrosclerosis. With regard to the relationship of diabetes mellitus to renal lesions and hypertension, it may be safely stated that from a study of our cases it is evident that diabetes mellitus either preceded or developed concomitantly with the intercapillary glomerulosclerosis. In one case diabetes mellitus existed for many years and was complicated by albuminuria, hypoproteinemia and edema before hypertension developed. This suggests that the changes in the glomeruli and renal vascular apparatus did not result from but preceded the hypertension. In contrast to the diabetes mellitus, the hypertension appears at a later stage, corresponding to the time when the renal vascular lesions have become advanced.

In 1935 Kimmelstiel³ described in the arteriosclerotic kidney a broadening and hyalinization of the intercapillary axial connective tissue. He interpreted the changes as an aging phenomenon of the glomerulus. It would appear that the changes observed in the patients under consideration represent an accelerated and advanced aging phenomenon, probably related to or possibly precipitated by diabetes mellitus. It has been recognized for some time that patients who have

mild diabetes mellitus and who have reached the fourth decade do have accelerated vascular changes in the coronary and peripheral arteries, and often with only mild degrees of hypertension; frequently the vascular changes are more pronounced in one area of the vascular tree than in another—the reason for which is not clear. Therefore it is suggested that the intercapillary changes in this group of patients may represent another instance of a predilective degenerative process occurring in mild diabetes mellitus which culminates in the syndrome under discussion.

CONCLUSIONS

1. Intercapillary glomerulosclerosis is an accelerated aging process occurring in mild diabetes mellitus and is accompanied by widespread arteriosclerosis.

2. The well developed syndrome is characterized by mild diabetes mellitus, albuminuria, varying degrees of hypertension, arteriosclerosis, edema and hypoproteinemia. The development of the renal changes alters the clinical course of an otherwise mild diabetes mellitus leading to a serious and progressive malady.

ABSTRACT OF DISCUSSION

DR. SOMA WEISS, Boston: Intercapillary glomerulosclerosis is primarily a descriptive term indicating a certain type of focal lesion of the renal glomerulus. Frequently, it is but an accidental microscopic finding without clinical significance. Glomerulosclerosis represents a degenerative process occurring usually in association with renal arteriosclerosis or arteriolar sclerosis with or without diabetes. It can be superimposed also on the usual lesions of glomerulonephritis. Intercapillary glomerulosclerosis assumes clinical interest only if the lesions described by Drs. Walker and Porter are prominent and diffuse. Such diffuse intercapillary glomerulosclerosis is prone to be associated with albuminuria, hypoproteinemia and a tendency to anasarca. This nephrotic syndrome of intercapillary glomerulosclerosis, in contrast to that of so-called lipoid nephrosis, occurs most frequently after the age of 40 and is often associated with some degree of hypertension. Hypertension, however, is not always present. Thus, it is known that broadening of the glomerular intercapillary connective tissue, a manifestation of an aging process, can be independent of arterial hypertension. Hypertension and the renal arteriolar lesions are independent of the specific lesions of intercapillary glomerulosclerosis, although they may all depend on a common primary cause. The combination of diabetes, nephrotic syndrome and vascular sclerosis makes the diagnosis of intercapillary glomerulosclerosis probable. In recent years, such correct diagnosis has been made on several occasions in the clinic. It is significant that here we are dealing with a type of nephrotic syndrome in which the causative lesion can be clearly placed within the glomerulus. The tubules are normal or contain some fat. The clinical syndrome of nephrosis is related to various types of renal disease in which the determining lesion is probably located in the glomerulus and not in the tubules. Thus, glomerulonephritis, amyloid renal disease, glomerulonephrosis of toxemia of pregnancy, lipoid nephrosis (although glomerular lesions of etiologic significance are denied by some) and intercapillary glomerulosclerosis are associated with glomerular lesions and the nephrotic syndrome. According to this concept, we should differentiate different types of nephrosis or nephrotic syndromes.

DR. PAUL KIMMELSTIEL, Richmond, Va.: I should like to speak about the differentiation of this lesion to one which, histologically and partially clinically, may be very similar to the intercapillary glomerulosclerosis, namely a certain type of subacute glomerulonephritis which Fahr and Volhard referred to as intracapillary glomerulonephritis. I had difficulty in distinguishing these conditions from each other during the first cases. The difference I was finally able to demonstrate is shown in lantern slides. The first one is from a case of intracapillary glomerulonephritis, a subacute phase, which clinically invariably is associated with a marked degree of nephrotic syndrome.

2. Newburger, R. A., and Peters, J. P.: Intercapillary Glomerulosclerosis: A Syndrome of Diabetes, Hypertension and Albuminuria, *Arch. Int. Med.* 64: 1252-1264 (Dec.) 1939.

3. Kimmelstiel, Paul: Glomerular Changes in Arteriosclerotic Contraction of the Kidney, *Am. J. Path.* 11: 483-496 (May) 1935.

There is a thickening of intercapillary connective tissue, just as in the intercapillary glomerulosclerosis, but the next slide shows the essential difference; namely, the peripheral capillaries are narrow and the basement membrane at the very periphery is split up. This process is one which does not spread from the hilus of the glomerulus as it does in glomerulosclerosis but is one which simultaneously involves all capillaries of the glomeruli, and therefore the peripheral capillaries as well as those in the center. In the next slide (high power) the peripheral capillary is shown to be split up and it is blurred, in contrast to the intercapillary sclerosis shown in the next two slides, in which the peripheral capillary appears as a fine line, which is not teased up and not blurred, the capillary being open rather than narrow. Although those conditions histologically as well as clinically are similar in many cases, they can easily be distinguished clinically as well as microscopically. I have observed about 12 cases of this disease in Richmond during five years, that, is within about fifteen to eighteen hundred autopsies. In my first investigation in Boston I saw 9 cases from autopsy material taken from the complete collection of the Mallory Institute from 1898 to 1934; I would say about ten times more autopsies. The seeming increase of frequency is easily explained. The cases selected in Boston were taken only from autopsies in which cardiac hypertrophy and arterial hypertension were noted during life and at autopsy. There were only 9 cases. The cases in Richmond, however, were selected consecutively throughout the entire time, and only about half of these cases really did show hypertension. Therefore I certainly agree with the authors' conception that hypertension is not an essential part of this disease and certainly does not cause it.

DR. SHEPPARD SIEGAL, New York: At Mount Sinai Hospital in New York we had been interested primarily in a clinical syndrome, and we then discovered that it was associated with the type of lesion presented here by Drs. Porter and Walker. In other words, we found that among diabetic patients there was an unusual incidence of the nephrotic picture. On study of these cases, of which it was possible to collect about 13, 5 of them which I was able to follow to necropsy all showed the typical kidney lesion just described. At present further study of this problem is being pursued from the postmortem point of view. Dr. Allen in the pathology department and I have studied 200 control cases, in none of which was diabetes present, 100 without hypertension, 100 with hypertension, and in none of the 200 cases was the lesion found at all. On the other hand, of 100 unselected diabetic patients whose kidneys were thoroughly studied, we found that 33 of them showed this lesion. They did not all show the lesion to the extent to which it has been present in the cases shown here; in some of them the lesion occurred in only a few glomeruli. Those cases in which the lesion was not extensive showed no element or no significant element of the syndrome as here presented. It is important to emphasize that the lesion may occur in diabetic patients without the syndrome. It seems to be correlated more with the diabetes than with either the hypertension or any of the other elements of the syndrome. But when the lesions are extensive it is true that then one is likely to have pretty much the fully developed syndrome which has been presented here.

DR. WILLIAM B. PORTER, Richmond, Va.: We are conscious of the fact that one is stepping on dangerous ground when one attempts to establish a clearcut syndrome when the disease is a chronic degenerative one. However, we feel that this clinical entity is fairly well established and can be recognized at the bedside, and one can anticipate that the pathologist will find what has been described by Dr. Kimmelstiel. There is one hitch in the differential diagnosis which has not been touched on, namely the differential diagnosis between subacute glomerulonephritis complicated by the nephrotic syndrome. That is a pitfall which is likely to creep into the differential diagnosis. We feel that there are two important features which should favor nephritis versus the syndrome of intercapillary glomerulosclerosis. Anemia is almost a universal finding in glomerulonephritis, whereas in intercapillary glomerulosclerosis anemia is not an important feature of the syndrome. The second and important point is that as a rule the nephrotic stage of glomerulonephritis is a disease which occurs in the age group under 50, whereas the majority of these patients are beyond 50.

TREATMENT OF UTERINE FIBROMYOMAS

WILLIAM E. COSTOLOW, M.D.
LOS ANGELES

Several years ago a report¹ was published on 604 patients with uterine fibromyoma treated between 1921 and 1926 by means of radiation therapy in our practice (Soiland, Costolow and Meland). Since that time 1,137 additional patients have been treated. A statistical analysis has been made of 1,009 of those treated between 1927 and 1937, with a follow-up of from two and one-half to twelve and one-half years. Of this group, 23 were either "lost" or impossible to follow for a two and one-half year period. However, several of these patients showed improvement when last examined, and we believe the final results would conform to the findings of the large group. It is doubtful if many of them were later operated on, as it is logical to assume that those patients who found treatment unsatisfactory would have returned. At any rate, in analyzing a large group of 986 cases, 23 missing is too insignificant greatly to affect the total average result. We have excluded patients with benign uterine bleeding and fibrosis uteri and those without uterine enlargement or nodular involvement. The size of the uterine masses in this series varied from small nodular uteri two times normal size to uterine masses the size of an eight months pregnancy.

The majority of our patients were referred by other physicians for radiation therapy. Hence most of the cases were selected especially for irradiation. One of the leading surgeons in our community has alone sent us over 200 patients whom he selected for radiation therapy instead of operation. During these years we saw, in addition, 204 patients to whom treatment was not given either because of some contraindication to radiation therapy or the patient's choice of surgical intervention. We believe the careful selection of cases is the most important single factor contributing to success in the treatment of fibroids by radiation therapy. The diagnosis of fibroid tumors should be established as definitely as possible before radiation therapy is commenced. With large tumors, this is often difficult, and we believe a good rule to follow is that in cases where doubt exists as to diagnosis, operation is the treatment of choice. We accepted a number of patients with the larger tumors, in the treatment of which radiation would usually be contraindicated, either because the patient refused to have an operation or a physical condition precluded surgical intervention. In many of these patients we have obtained surprisingly good results.

Radiation has been used successfully for many years in the treatment of certain uterine fibromyomas, and the gynecologic literature from all parts of the world is replete with reports on its success as a method of treatment in this condition. On the other hand, surgical intervention has also proved to be a satisfactory means of treatment, even though it carries a low but definite morbidity and mortality rate. A number of patients no doubt require operation; nevertheless many may be treated by radiation therapy with less morbidity and mortality.

From the Los Angeles Tumor Institute, 1407 South Hope Street.
Read before the Section on Radiology at the Ninety-First Annual Session of the American Medical Association, New York, June 12, 1940.
1. Soiland, A.; Costolow, W. E., and Meland, O. N.: *California & West. Med.* 20: 234 (April) 1929.

Taylor² stated that "there should be no quarrel between the surgeon and the radiologist over the treatment of fibroid tumors—indications will become more clearly defined." Contraindications to irradiation have been established for many years and handed down through the literature. Some of these are definite and can be easily followed. Others, however, possibly are too rigid to be exactly substantiated, and patients for radiation therapy are no doubt being selected too conservatively.

Some of the factors which have been employed in the choice of a method for treating fibroid tumors are age of the patient, size and type of tumor, presence of associated pelvic disorders and effect of menopausal symptoms on the patient. It is our purpose to consider these factors in this report, together with any after-effects on the remaining uterus or residual fibroid masses in regard to later bleeding and pressure symptoms, or the subsequent development of disease.

AGE OF PATIENT

Of considerable importance in deciding between radiation therapy and surgical intervention is the age of the patient. In younger women it is, of course, desirable to attempt to preserve not only ovarian function as much as possible but in some cases also to preserve the child-bearing function. Myomectomy often achieves the desired result. The observation of Bland Sutton made many years ago that "after enucleation of a fibroid in the procreative period of life, a woman is more likely to grow another fibroid than to conceive successfully" is not exactly in keeping with more recent surgical reports. Bonney³ reported that in a series of six hundred myomectomies for fibroid tumors only 10 patients had recurrences, and in 137 married women a total of 52 (38 per cent) became pregnant. Counselor⁴ of the Mayo Clinic stated that according to statistics 35 per cent of the patients do become pregnant following myomectomy. Recurrences of myomas took place in 20 per cent of the patients younger than 40 and in 8 per cent of those more than 40 years of age.

Fortunately, the majority of uterine fibroid tumors occurs in women around 40, or near the menopausal age, when the preservation of ovarian function is unimportant. In a former series¹ the average age was 43.2, and in this series (1927 to 1937) 42.5 years, with only 26.7 per cent under 40 and 73.3 per cent over 40 years.

Hence consideration of menopausal symptoms was not so important in our series inasmuch as 73 per cent of these patients were in the menopausal age. Fibroid tumors probably occur fairly often in women in their earlier years, but in the majority of cases symptoms necessitating treatment do not arise until around the menopausal age.

ASSOCIATED PELVIC INFLAMMATION

For many years a history of previous pelvic inflammation has been mentioned in the literature as a contraindication to radiation treatment of uterine fibromyomas, but little proof has been shown of any acute infections occurring after irradiation. The fact that preexisting adnexal inflammation is present in fibromyoma has been established beyond doubt. In 150 consecutive patients with fibromyoma operated on at

St. Luke's Hospital, Wood⁵ found chronic adnexal infections in only 28 per cent. Other reports (Ford⁶) have shown evidence of as high as 40 per cent associated chronic inflammation in patients.

Theoretically, dilation and curettage with insertion of radium might stir up preexisting chronic inflammation. There is, however, no reason why external roentgen ray therapy should do this. In fact, this method of therapy has been successfully used in the treatment of chronic pelvic inflammation. In our series of 986 cases, in only 1 did there develop an acute inflammatory process after irradiation. The inflammation in this patient followed curettage and the insertion of radium. No acute inflammation resulted in any patient treated externally by means of roentgen rays alone. Inasmuch as 61.5 per cent of our patients were treated by radium given intrauterinely plus roentgen rays, and 5.5 per cent by radium alone, the importance of associated pelvic inflammation as a contraindication is difficult to understand.

TECHNIC

In our series, 61.5 per cent of the patients were treated by both radium and roentgen rays; 33.0 per cent, by roentgen rays alone, and only 5.5 per cent, by radium alone. In the use of both roentgen rays and radium, only small doses of each are necessary. Curettage to rule out malignant disorders as well as to discover the presence of submucous fibroid growths is important. This should be a routine procedure in practically all cases of uterine fibromyoma. If curettage is done, the application of radium at the same time is simple. In patients with severe hemorrhage, radium combined with roentgen rays will often produce a more rapid cessation of bleeding than roentgen rays alone. Usually the large tumors are better treated with roentgen rays alone. In these, because of the intervening distance, radium inserted intrauterinely may not be suitable for applying a sufficient dose to the ovaries. The amount of radium applied intrauterinely is small, approximately 1,000 to 1,200 milligram hours. An applicator with two 25 mg. radium tubes in tandem and a filtration equivalent to 1 mm. of platinum is used. This prevents strong reactions on the endometrium which might produce atresia of the canal or later leukorrheal discharge. The roentgen dose averages from 400 to 500 roentgens in the mid-pelvis. Increased doses were used occasionally in the large tumors. However, it is doubtful if much additional shrinkage was obtained in them from the greater amount of irradiation action on the tumor cells themselves. The cells in this type of tumor when located in other parts of the body are resistant to irradiation, and the same principle probably applies here. Some questionable evidence exists to show that even after menopause irradiation shrinkage may be induced in large tumors. A case in point in our series is as follows:

A woman aged 50 with a chief complaint of uterine tumor the size of a 4 months pregnancy applied for treatment in July 1933. She had ceased to menstruate three years previously and had had hot flashes and evidences of menopause. For the past two weeks she had noticed slight spotting of blood and pressure symptoms. Curettage was negative for malignant growths and radiation treatment was instituted. A recent examination of this patient, six and one-half years later, revealed the uterus to be atrophic.

However, most shrinkage is undoubtedly produced by the action of the rays on the ovaries with the production of the menopause.

6. Ford, F. A.: *Surg., Gynec. & Obst.* 42: 245 (Feb.) 1926.

tomless tumor will later cause any difficulty to the patient. Inflammatory degeneration of remaining fibroid masses is rare. In our experience, fibroid tumors the size of a 4 months pregnancy or larger are the only ones in which this has occurred, and we have observed only two such instances. Large, irregular, or multiple pedunculated tumors are more likely to degenerate, and consequently patients with these should be operated on if possible.

The determination of the size of the tumor by bimanual examination cannot be entirely accurate, and it is really a matter of estimation. The size of the tumors in our series varied from that of a 3 months or less to that about the size of an 8 months pregnancy. No case was included unless the uterus was either definitely enlarged to at least twice normal size or, although the uterus was small, definite nodules could be palpated proving the tumor to be a true fibroid.

In ascertaining the decrease in size after treatment, the estimations of 25 per cent, 50 per cent and 75 per cent reduction used in the large tumor group are probably open to question, but these calculations were made after examination. The after-treatment group designated as "slight enlargement of uterus remaining" included those patients in whom a slight irregularity or nodulation of the fundus could be felt or in whom the uterus was still enlarged less than twice its normal size.

Tables 1 and 2 are self explanatory and show the effect of irradiation in regard to reduction in size of the tumor in the various groups, the number of patients operated on, the occurrence of pressure symptoms and the percentage of relief. The size of the tumor and the number of cases of each type are as follows: 3 months' pregnancy or less, 722; 4 months' pregnancy, 149; 5 to 6 months' pregnancy, 107; 7 to 8 months' pregnancy, 8.

CANCEROUS DEVELOPMENT IN THE UTERUS AFTER RADIATION THERAPY

There is no evidence to lead one to believe that uterine cancer occurring after radiation therapy is a serious

TABLE 3.—Patients Operated On After Radiation Therapy
(Tumor Size of Three Months' Pregnancy or Smaller)

Total number of cases.....17 or 2.4%	
Number of Cases	Findings and Indications
3	Ovarian cyst: size of tumor unchanged and pressure remained
3	Submucous fibroids: bleeding continued
3	Carcinoma of the fundus: bleeding later: 3 months, 1 year and 5 years after treatment
1	Carcinoma of cervix: developed 6 years after treatment
1	Intestinal obstruction: 3 years after treatment (tumor adherent to intestine)
2	Carcinoma of ovary: irregular bleeding continued
4	Tumors remaining without relief of pressure symptoms

consideration. This occurred in only 4 cases in our series (table 3). This number is probably well within the normal limits of carcinoma in an age group comparable to our series of patients, three fourths of whom are in the "cancer age." In this group, in 3 patients carcinoma of the fundus developed three months, one year and five years respectively after radiation therapy, and one patient suffered carcinoma of the cervix six years after treatment. A larger percentage of other types of carcinoma than carcinoma of the uterus occurred. In 6 patients there developed later carcinoma of the breast, in 1, of the kidney, and in 1, of the stomach. Norris and Behney⁷ found that in only

7 out of 485 patients previously treated by irradiation did carcinoma develop. Macfarlane¹³ observed that the incidence of carcinoma was only 0.35 per cent in 3,890 patients treated by irradiation in German clinics, whereas cancer may occur normally in as high as 5 per cent of women in the "cancer age." Sarcomatous degeneration is very rare. In 112 patients with large tumors Corscaden¹¹ found no late sarcomatous degeneration. Pfahler¹⁴ has even suggested that irradiation may afford a distinct protection against later development of cancer in the uterus. It is well known that

TABLE 4.—Patients Operated On After Radiation Therapy
(Tumor Size of 4 Months' Pregnancy or Larger)

Total number of cases.....11 or 4.8%	
Number of Cases	Findings and Indications
7	Symptoms of pressure or bleeding not relieved
1	Ovarian cyst: masses increased in size
1	Dermoid cyst: large mass removed
2	Degeneration (inflammatory) of fibroid mass occurred

carcinoma occasionally occurs in a cervical stump after supravaginal hysterectomy (2 per cent in Polak's series and 0.27 per cent in Hochman's series¹⁵). From our experience and from available data there is little reason to believe that cancer is more likely to develop in the uterus remaining after radiation therapy than in the remaining cervical stump after hysterectomy or in the normal uterus of any woman in the "cancer age."

Tables 3 and 4 show the cases in which operation was later performed, together with indications for operation and the findings. It can be seen that an incorrect diagnosis was the reason for the majority of failures. Fortunately the group is small. In my entire series of 986 cases operation was necessary in only 2.8 per cent.

SUMMARY

1. An analysis was made of 986 patients with uterine fibromyoma treated by radiation therapy between 1927 and 1937, with a follow-up period of from two and one-half to twelve and one-half years.

2. Correct diagnosis should be established before radiation treatment is commenced; if doubt exists as to diagnosis, operation is the treatment of choice.

3. Some contraindications to radiation treatment of uterine fibroid tumors are definite and should be followed; others are possibly too rigid to be exactly substantiated, and patients for radiation therapy are probably being selected too conservatively.

4. The average age of our group is 42.5 years, approximately 75 per cent of the patients being over 40 and, therefore, in or near the menopausal age. We believe that irradiation menopause is no more troublesome than normal menopause. Sexual function is not destroyed.

5. Preexisting pelvic inflammation is not a justifiable contraindication to radiation therapy. Acute pelvic inflammation after irradiation occurred in only 1 patient in our series.

6. In only 4 patients (0.4 per cent) did cancer of the uterus develop after radiation therapy. A remaining uterus or residual mass is no more likely to become cancerous than a normal uterus in a woman of the "cancer age."

13. Macfarlane, Catharine: *Am. J. Obst. & Gynec.* 23:108 (Jan.) 1932.

14. Pfahler, G. E.: *Am. J. Roentgenol.* 31: 51 (Jan.) 1934.

15. Polak and Hochman, cited by Danforth, W. C.: *Am. J. Obst. & Gynec.* 28: 409 (Sept.) 1934.

7. Inflammatory degeneration of large fibroid tumors occurred in 2 patients. In both cases, operation was later carried out successfully.

8. In tumors the size of a 3 months pregnancy or smaller (722 cases), there was a reduction of the uterus to normal in 84.3 per cent and to normal or only slightly enlarged (less than twice normal) size in 93.5 per cent. Only 2.4 per cent of patients with these tumors were later operated on.

9. In patients with tumors the size of a 4 months pregnancy or larger (264 cases) there was a reduction of the uterus to normal in 36.7 per cent and to normal or slightly enlarged (less than twice normal size) in 52.7 per cent. Only 4.2 per cent of this group were later operated on. In tumors of this size roentgen rays alone, preceded by curettage, are the most satisfactory method of radiation therapy.

10. Careful selection of cases is the most important single factor contributing to the success of radiation therapy for uterine fibromyoma.

ABSTRACT OF DISCUSSION

DR. WILLIAM P. HEALY, New York: I should like to commend this paper to all surgeons and gynecologists. It represents an unbiased analysis of a large enough series of cases to indicate what can be done to cure nonmalignant tumors of the uterus in a conservative manner, protecting patients for whom the risk of major surgery may be very grave. There was no mortality in this series of cases. The size of the tumors included is interesting. Some of them were as large as an eight months pregnancy. I endorse the author's statement regarding the diagnosis of the tumor mass. It is interesting that in his report of 986 cases treated by irradiation there was only one case in which some inflammatory disturbance seemed to result from the treatment. We may therefore say that in the hands of competent therapists irradiation may be carried out safely without fear of a complicating inflammatory disturbance. In only 5 per cent of the cases was radium alone the therapeutic agent. In the remaining 95 per cent of the cases, either roentgen rays alone or roentgen rays in combination with radium were used. Actually, 65.5 per cent of the patients were treated with radium plus roentgen rays. My feeling has been that, if the tumor is the size of a three months gestation or larger, roentgen therapy should be combined with the introduction of radium into the uterus. Diagnostic curettage is essential before subjecting the patient to any other form of therapy, because we must rule out a possible cancer in the cervix or corpus. Severe bleeding is best controlled with radium and curettage plus roentgen rays. In the larger tumors roentgen rays are necessary because radium alone will not bring about castration, and if we do not establish castration we shall not terminate the growth of the tumor mass. I would not recommend irradiation for myomatous tumors after the menopause despite the good results obtained in this series of cases, because cancer of the corpus is a common lesion after the menopause, and 38 per cent of my patients with cancer of the corpus have had coincidental myomatous tumors in the uterus. The risk of an error in diagnosis is very grave.

DR. CHANNING W. BARRETT, Chicago: We have heard from the Far West, from the Far East. I ask the privilege of the floor for fear, if the momentum gets started, you will not know there is such a thing as surgery for fibroids of the uterus. Some twenty-nine years ago, I remember a man rushed into the meeting of the gynecologic section at Washington and asked the privilege of the floor; seemingly he could not wait. He said "I hold in my hand a capsule that is going to change gynecology entirely. There will practically be no more operating for fibroids of the uterus." He acted as though anxious to get back and get that capsule working for fear some patient might not receive its benefits. I won-

dered at the time how much of that was overoptimism. A few years later Gauss of Germany said "I have something that does away with surgery for fibroids of the uterus," and men went over there to see Gauss and his work. They came back and equipped themselves. A good many of them have discarded it. Some of them read papers on their work with fibroids treated with roentgen rays, and now they have discarded them and have no more use for them except in rare cases. There are indications for radium and roentgen rays, and there certainly are indications for surgery. What does one want in this condition? A live patient, certainly: a woman with all her functions left that can be left. If the uterus can be saved, we want to save it. If we can save the ovaries and take out the uterus, we want to save the ovaries, for in them is the estrogenic function which keeps her a woman, the feminizing function. And now we think of irradiation. Is it such a benign thing? It is the most radical thing you can do to a woman; it practically takes out her ovaries and her uterus. There is no conservatism there, and it leaves the fibroid set to degenerate. Degeneration is a crying evil of fibroids and irradiation increases it. What are the real indications for treatment with radium? A woman who is near the menopause who has a small fibroid, bleeding but with no other symptoms, no degeneration and no complications. One cannot treat a woman before the age of 40 with this and do justice to her, because irradiation will destroy her child-bearing and ovarian function. If there is a small fibroid present that is giving symptoms, the most conservative thing one can do to the patient is to take out the small fibroid surgically.

DR. ARTHUR H. CURTIS, Chicago: I am rather in accord with the sense of Dr. Barrett's remarks. With added years I find more and more instances in which an apparently simple case of uterine fibroids turns out to be a malignant growth or an ovarian tumor or an endometriosis which would be better treated by surgery than with radiation. I believe this whole problem can be summarized as it is seen by gynecologists throughout America whose opinion, experience and advice we would wish to follow by saying that radiotherapy in these cases is indicated chiefly for women who are at or near the menopause, who have a bleeding tumor of a size not exceeding the uterus of a three or three and one-half months pregnancy; when radiotherapy is given there should always be a preliminary diagnostic curettage.

DR. WILLIAM E. COSTOLOW, Los Angeles: Dr. Healy mentioned the treatment of tumors after the menopause. There was only one case in the series in which this occurred, and the report is given in the paper. This case was cited to indicate that possibly some of the effects of irradiation may be from direct action of the rays on the tumor cells instead of all the effect being due to the action on the ovaries. I presented the results in a large series of cases, the majority having been selected especially for radiation therapy by surgeons and gynecologists, but I did not advocate irradiation for all fibroids. I mentioned that one surgeon in our community had sent me over 200 cases of fibromyoma. Certainly he did not refer all of his fibroid cases for radiation therapy but selected those for which he felt the conservative type of therapy was indicated. Time does not permit me to reply to all the arguments which Dr. Barrett has presented. However, if he will carefully read the paper I have just presented he will there find my answers to most of his contentions. I agree with Dr. Curtis in his remarks about the treatment of young women and very large tumors. As I pointed out in the paper, 75 per cent of the patients were past 40 and in the menopause age, the average age being 42.5 years. The small tumors are the ones which should be selected for radiation therapy; the large tumors frequently cause the radiologist to get into difficulty. Dr. Curtis mentioned the danger of malignancy occurring later if the uterus is not removed. As brought out in my presentation, this occurrence has been less than the normal incidence of uterine cancer, for in 1,009 cases, 986 of which were followed from two and one-half to twelve and one-half years, cancer of the uterus developed later in only 4 cases (0.4 per cent).

THE BODY ECONOMY OF VITAMIN C
IN HEALTH AND DISEASE

WITH SPECIAL STUDIES IN TUBERCULOSIS

HENRY C. SWEANY, M.D.

CHARLOTTE LOUISE CLANCY, M.D.

MOLLY H. RADFORD, M.D.

AND

VIOLA HUNTER, M.Sc.

CHICAGO

During the past generation most of the diseases due to a deficiency of accessory food factors have been brought under control, and within the last decade many of the active principles concerned have yielded the secrets of their chemical structure. Not the least of these is the antiscorbutic substance, or "water soluble" vitamin C, a principle known to exist in limes and lemons for over a hundred years and recently found in abundance also in a large number of fruits and vegetables and in animal tissues.

As healing in tuberculosis is characterized largely by the formation of connective tissue, and the latter, according to Wolbach and his associates,¹ is formed by the action of vitamin C on fibroblasts, it does not seem unreasonable to suspect that a vitamin C deficiency may be one of the causes of unfavorable trends in tuberculosis, if it does not actually contribute to exacerbations of the disease. By the same line of reasoning, a replenishment of a deficiency of vitamin C, not to mention its administration in excess, may help at least to change the disease from an unfavorable course to a more favorable one.

With these possibilities in mind, a plan of study of the problem was undertaken which involved many experiments on the economy of vitamin C in health and disease in addition to extensive therapeutic experiments made in a large series of cases of pulmonary tuberculosis.

PREVIOUS WORK WITH VITAMIN C IN
TUBERCULOSIS

The report to follow represents only a summary of this combined study. A preliminary phase of the work has already been reported² on the results of blood examination during the early period of treatment. A slight hematinic value of vitamin C was found to exist after the beginning of treatment and to persist for the

first few months. Although experimental studies³ show that vitamin C deficiency enhances the development of tuberculosis in guinea pigs, reports in the literature with regard to therapeutic benefits of vitamin C on tuberculosis are not convincing. Petter⁴ reports favorably in a series of children, most of whom had surgical or lymph node tuberculosis. He gave the ascorbic acid in a malted milk mixture, without any controls. Hasselbach⁵ made an extensive study of the therapeutic value of ascorbic acid on 70 patients with various types of tuberculosis. He especially recommends its use for patients with a tendency to small seeping hemorrhages. Unfortunately, his study was complicated by a simultaneous administration of calcium. He reported that patients with a good prognosis and with no deficiency but stationary in their disease course were benefited. The effect in such cases is reputed to be that of a general tonic. If there is a measurable deficiency, the effect of vitamin C is more obvious. Finally, he combines it with gold therapy, especially when there is a tendency for hemorrhages to develop. Like many others, Hasselbach did not report controls. Sande⁶ also recommended its use with gold therapy to reduce the tendency to form hemorrhages.

Heise, Martin and Schwartz⁷ found that there was a greater decrease in the sedimentation of red blood cells in treated patients over controls, but that there was no noticeable clinical improvement after treatment with vitamin C.

Sebok and Pretzai⁸ state that the long continued fever and increased metabolism in tuberculosis causes a depletion in the vitamin C reserve, but that in 20 cases only 2 could be found with true hypovitaminosis. The extreme deficiency is usually from 3 to 4 Gm. The same authors also report that ascorbic acid was given with good results in pulmonary hemorrhages. For a rapid removal of the deficiency large doses of ascorbic acid are given, but lemon juice is used to maintain the normal level after it approaches this level.

Trautwein⁹ found that his febrile patients had a vitamin C deficiency of from 1,800 to 3,600 mg., for which he gave from 150 to 200 mg. a day, injected intravenously to restore the level to normal. After such treatment a decided improvement was indicated by a gain in weight, fall of temperature, decrease in red cell sedimentation rate and a favorable trend in the blood pictures. Liver function improved as the result of a more favorable effect on the storage of glycogen. Bauer and Vorwerk,¹⁰ however, treated a series of patients and concluded that a "final judgment of the therapeutic value of vitamin C in tuberculosis cannot yet be passed."

From the Research Department of the City of Chicago Municipal Tuberculosis Sanitarium, Dr. Frederick Tice, president, Board of Directors (Dr. Sweany) and the Department of Physiology, University of Chicago, Dr. A. J. Carlson, chairman (Dr. Clancy, Dr. Radford and Miss Hunter).

Read before the Section on Pathology and Physiology at the Ninety-First Annual Session of the American Medical Association, New York, June 14, 1940.

Dr. Eugene deSavitch was largely responsible for suggesting this study and also for obtaining financial assistance from the California Fruit Growers Exchange. Generous subsidies were received from the California Fruit Growers Exchange. Mr. A. J. Lorenz not only helped to negotiate the subsidies but assisted with many technical details of analysis. Dr. Frederick Tice cooperated in carrying out the work at the Chicago Municipal Tuberculosis Sanitarium. Dr. A. J. Carlson gave sound advice. Mr. Charles Steinmetz assisted with the chemical analyses.

Its action, if any exists, is not specific but improves the general conditions.

In order more completely to understand the role of vitamin C in tuberculosis, it seemed desirable to know many facts concerning its economy in health and disease.

THE NORMAL DAILY REQUIREMENTS OF VITAMIN C

Most of the earlier studies devoted to the determination of the daily requirement of vitamin C were based on a quantity required to prevent gross clinical symptoms. According to the work of Harris and his co-workers¹¹ from 25 to 35 mg. is the minimum amount for normal persons. Most workers, however, claim that from 55 to 60 mg. a day is more nearly the optimum quantity for a good state of health, although much less may prevent scurvy. Van Eekelen's¹² figure of 0.84 mg. and Heinemann's¹³ of 0.85 mg. per kilo-

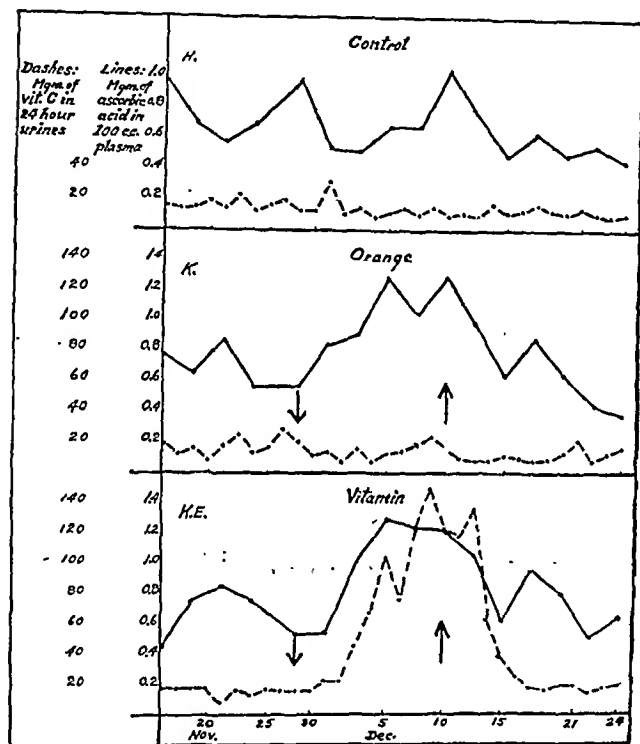

Chart 1.—Course in three representative cases showing one control (H). Note that the level in the urine fell from about 15 to 11 mg. in twenty-four hours and the blood fell from 1.0 to 0.6 mg. One of the orange group (K) failed to saturate after the administration of 2,750 mg. extra ascorbic acid. The blood curve rose promptly but soon fell when the ascorbic acid was stopped. The urine curve did not rise at all. One subject received ascorbic acid (vitamin) who showed nearly normal saturation (K. E.).

gram, amounting to about 60 mg. a day, are accepted as the optimum minimum by most experienced workers. The low level recommended by Harris (25 to 35 mg.) may be considered as an indispensable minimum to prevent the first sign of scurvy, while the higher level (50 to 60 mg.) is more nearly the optimum to maintain a good state of health. It is being recognized that patients do not need to be scorbutic to suffer from avitaminosis C. King¹⁴ says "The fact that there is a wide zone of vitamin C deficiency between scurvy and

optimum health, is of more interest in relation to human health than the problem of clinical scurvy." Rinehart and Mettier¹⁵ state that a depressed ascorbic acid level may be a "necessary background for rheumatic fever." Although the optimal daily requirement has been established, it furnishes only a starting point for a determination of the daily balance and a total quantity of vitamin C in the body.

THE DAILY REQUIREMENTS OF VITAMIN C IN TUBERCULOUS INDIVIDUALS

Heise and his associates,¹⁶ Trautwein,⁹ and others have recommended rather empirically the administration of from 150 to 200 mg. of vitamin C a day in severe tuberculosis to care for the requirements, but no accurate daily balance has yet been worked out.

To help solve this problem, many experiments were performed, some of which will be reported. Both early and advanced cases were studied. In the early cases there was but little unsaturation and they are omitted in this report. A summary of the results in the far advanced B and C cases, consisted of 30 cases arranged as follows: Five men and 5 women were studied for six weeks to establish a normal "base line" for our diet; another similar group was run for two weeks, then given orange juice containing approximately 250 mg. of ascorbic acid for a period of two weeks; and then for two weeks the blood and urine were allowed to return to the base line. The third similar group received 250 mg. of crystalline vitamin C in twenty-four hours in the second two weeks instead of the orange, to see if there were substances in oranges that behaved differently from the pure substance. The blood and urine observations of representative cases of each group are shown in chart 1.

Representative controls of both men and women revealed a blood content of around 0.8 mg. per hundred cubic centimeters of blood at the beginning of the experiment, which underwent a slow decrease on the general diet to about 0.5 mg. after about four weeks and a much slower drop after that. The corresponding urine curve ranges from about 18 mg. at the beginning to about 10 mg. in twenty-four hours during the same interval. The general diet proved to be inadequate in vitamin C because there is a slow fall of the blood and urine curves after the beginning of the experiment to levels that are reported by van Eekelen,¹² Harris¹⁷ and others to represent unsaturation.

The orange and vitamin blood curves were generally sufficiently alike to describe together. There was a slight drop at first from about 1.0 to 0.6 mg. per hundred cubic centimeters of blood. After the beginning of the administration of the vitamin-containing drinks the blood curve rose sharply for about four days to about 1.5 mg. and remained at this level until the treatment was stopped. The curve then began to return toward the normal, at first quickly, then slowly, over a period of ten to twelve days.

In the majority of cases the urine curves began to rise from the base line about four to six days after the rise in the blood curve, suggesting that there was from 750 to 1,250 mg. of unsaturation if no allowance was

made for any destruction of the vitamin C. The quantity mounted sharply to from 140 to 220 mg. and then "leveled off," forming a few peaks, and decreased abruptly from two to four days after the treatment was stopped. It was near the base line in another four days. The high level reached is from 60 to 150 mg. less than the total intake.

These conditions prevailed among 6 women and 3 men. Two other cases showed irregular curves and a slight lag before appearing in the urine in from six to eight days (from 1,500 to 2,000 mg. unsaturation). Of 2 men the kidney threshold was not reached until eight and ten days respectively (from 2,000 to 2,500 mg. unsaturation), when a slight amount appeared in the urine. Two subjects, 1 man and 1 woman, showed no increase at all in the urine, indicating that they were not saturated enough to spill vitamin C in the urine even after receiving 250 mg. a day of extra ascorbic acid for eleven days (2,750 mg.). The blood content rose in all cases to the usual level, which proved that the ascorbic acid was not destroyed in the gastrointestinal tract.

Over and above the low intake in the general diet the rate of unsaturation seemed to vary roughly with the acuteness and extent of the disease. Two subjects became almost completely unsaturated in eleven days. Judging from van Eekelen's work,¹² the unsaturation in these cases on a diet containing 31 mg. of ascorbic acid occurred in about one-fourth the time it took to unsaturate normal human beings on a vitamin C free diet.

Similar conclusions have been shown by Heise and Martin,¹⁶ Trautwein⁹ and others.

UNSATURATION DUE TO LACK OF INTAKE ASSOCIATED WITH CERTAIN TUBERCULOUS PATIENTS

Another study was undertaken in certain complications and associated diseases in which a vitamin C deficiency might be expected as the result of a lack of intake in addition to the activity of the disease. In addition, it was desirable to remove the objection concerning the destruction of vitamin C in the gastrointestinal tract following administration by mouth.

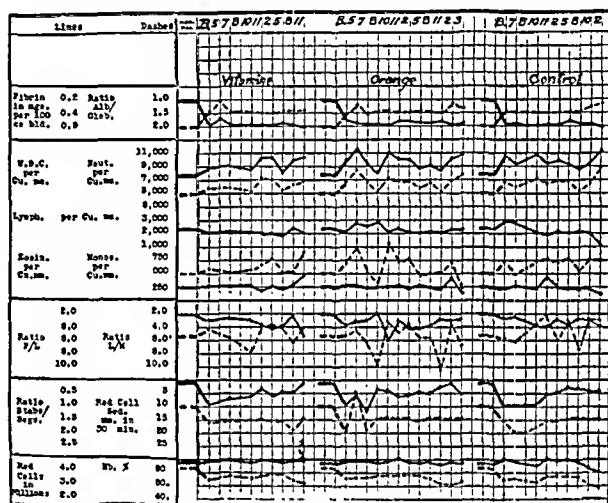

A rapid and direct method of testing unsaturation recommended by Barron¹⁸ was used, so that the status of a patient at any time could be ascertained with reasonable certainty. Instead of using sodium ascorbate, however, 500 mg. of ethyl-amine-ascorbate (cenolate-Abbott) was injected slowly intravenously and the urine tested after six hours for total vitamin C, after the method of Goldsmith and Ellinger.¹⁹ According to Barron's method, a recovery of less than 10 per cent in twenty-four hours represents unsaturation. Goldsmith and Ellinger found that about 60 per cent of the total injected is eliminated within six hours. Wright and his associates²⁰ have contributed the added information that the elimination is much slower in nephritis with retention. If 5 per cent or more, therefore, is eliminated within six hours and the patients are found to be free from nephritis, there should be no detrimental unsaturation.

The results revealed that nearly 70 per cent of the series selected were partly or wholly unsaturated. Of 26 subjects, 3 were completely unsaturated (below

5 per cent recovery), 8 were poorly saturated (6 to 15 per cent recovery), 7 partly saturated (16 to 30 per cent recovery) and 8 "adequately" saturated (30 to 68 per cent recovery).

The unsaturated or poorly saturated subjects were all on a poor vitamin C intake. One alcoholic addict with terminal tuberculosis was absolutely unsaturated. The patients on "nonresidue" and "general" diets for enteritis were also low. One peptic ulcer patient was unsaturated, another was low, but two others were surprisingly high.

A group of 15 critically ill patients was similarly studied with even more striking results, because in the last thirty days of life there is frequently little or no food eaten. Two subjects ran regularly between 0.3 and 0.4 mg. per hundred cubic centimeters of plasma with the urine running lower than 8 mg. in twenty-four hours. One of these patients was studied on till death, after which the organs were analyzed for vitamin C. Seven days before death she was given 500 mg. of ethyl-amine-ascorbate intravenously on three successive days without any appreciable rise of vitamin C in the

scurvy, multiplied by the daily elimination. It has been found to require about ninety days in man to reach the scorvic state. Assuming, therefore, that from 10 to 20 mg. a day is eliminated in the urine and a comparable quantity eliminated in the sweat and feces, there would be a loss of between 1,800 and 3,600 mg., an amount consistent with the estimate of Trautwein⁹ and of Sebok and Preztai.⁸

Another method is just the reverse of the preceding, viz., the amount necessary to saturate an unsaturated individual. The work of van Eekelen¹² reveals that in a decidedly unsaturated person it requires from 2 to 4 Gm. of vitamin C before any appreciable amount appears in the urine.

THE RESULTS OF ANALYSIS OF ORGANS FOR VITAMIN C

Although no record of a complete assay of the vitamin C of the whole body has been made, the content of separate organs has been determined by Yamagami²¹ and Birkhaug²² in guinea pigs and by Yavorsky, Almaden and King²³ in both guinea pigs and organs from a large number of human autopsies. In these reports the adrenals have been shown to possess the highest amount of ascorbic acid (about 0.5 mg. per gram of tissue). The larger organs (brain, liver, lungs,

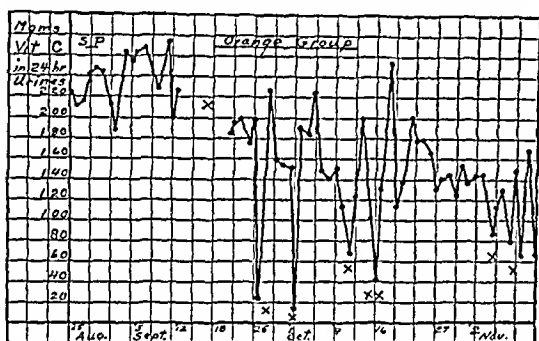

Chart 3.—A midsection of a curve of one of the vitamin C cases of the second mass experiment. Note that the curve on the left has as high as 250 mg. elimination a day in the urine, but it drops to 140 mg. near the end. The intake during that time was at least 300 mg. a day. The crosses indicate the days on which treatment was not given.

spleen, kidneys) are lower in content but seem to be more important depots of the body because of their size. These organs have from 0.1 to 0.4 mg. per gram of tissue.

By availing ourselves of the standard table of tissue weights of Vierordt²⁴ it may be crudely estimated from the reported studies on vitamin C in organs that there are from 3 to 6 Gm. of total ascorbic acid in the normal young adult human body.

AN ATTEMPT TO DETERMINE THE TOTAL VITAMIN C IN THE BODY

In order to test these rough figures for "saturated" persons and see if the total amount of vitamin C could be found in different diseases, especially tuberculosis, analyses were performed on the organs and tissues of 32 bodies coming to autopsy. Because of a lack of

space, histories of the patients and detailed analyses are omitted. All but 1 case (a monocytic leukemia) presented some form of tuberculosis. Two of the cases showed diabetes, in one of which also there was myocarditis, and some showed amyloidosis as well as the tuberculosis. One patient died suddenly in a pulmonary hemorrhage, after the disease was nearly arrested.

Bessey's²⁵ method for tissue analysis was used, but care was taken to keep the p_H below 1.5. Over that figure a complete recovery was not possible in certain tissues, as liver and spleen. The difficulty was overcome by using 7 per cent metaphosphoric acid instead of the 3 per cent advocated in the original method. Duplicates were run on many specimens by Bessey and King's²⁶ trichloroacetic method. The "tough" tissues, especially skin, were frozen in liquid nitrogen and pulverized according to the method of Graeser, Ginsburg and Friedmann.²⁷ Duplicate analyses were run on most specimens. The results are arranged roughly in the order of the tissue content of vitamin C.

The "vital tissues" were found to contain the most vitamin C. Hypophysis, adrenal, gonads, pancreas, spleen, liver and brain contain the substance, ranging from about 50 to 90 mg. in the first three to about 20 to 40 mg. per hundred grams of tissue in the last four. The largest depots of the body, however, are muscle and fat, with bone and skin also playing a role. In advanced disease these tissues lose nearly all their reserve and the bulk of vitamin C is found in the brain and liver, although the more vital cells still have the highest concentration. By using Vierordt's²⁴ standard tables of tissue weights we estimated the content of the bones and muscles. The content of the skin was determined by a special method to be reported later, based on Benedict's tables of the body area. Other tissues were estimated directly or by difference.

The results indicate that advanced active tuberculosis is devastating on the vitamin C reserve, reducing the total quantity to less than 300 mg. even on a fair vitamin C intake. On the other hand in a fatal case of monocytic leukemia there was 2,725 mg. (70 per cent saturation) at death. Another well nourished patient with quiescent fibroid tuberculosis with mild diabetes, who was on a high vitamin C diet, had 3,670 mg., or about 5 mg. per hundred grams of body tissue. These last figures were used arbitrarily as a saturation limit. The other cases ranged in between the two extremes and varied roughly with the intake of vitamin C.

THE EFFECT OF VITAMIN C ON THE DISEASE TUBERCULOSIS

The preceding preliminary studies, as well as the reports of others, justified a trial of vitamin C on various types of tuberculous patients. Although most authors agree that there is an increased requirement, there is no uniform opinion regarding the therapeutic value of vitamin C in tuberculosis. When viewed critically there are few therapeutic attempts that are free from objection on one point or another. Most of the reports suffer from a lack of controls, which is serious in a disease in which, according to Braeuning²⁸ about

30 per cent heal spontaneously without any treatment whatever. Another objection to the work already reported is that with few exceptions the reports do not include enough cases to rule out the variability inherent in the disease.

SELECTION OF PATIENTS

In order to approach an ideal experimental result, the patients were carefully selected, grouped and evenly matched as to quality and quantity of the disease.

The first consideration was with regard to the natural status of the patient. This included age, sex, race, environment and constitutional factors, each of which was appraised numerically with arbitrary values and recorded on a special chart for that purpose.

Laboratory examinations, especially blood counts and chemistry, careful roentgenologic studies and clinical observations were recorded throughout the three successive mass experiments, one of which will be presented.

THE FIRST MASS THERAPEUTIC EXPERIMENT

The details of the selection were as follows: There was a group of 111 cases chosen, from which 102 were finally selected for the experiment and 98 actually used. These cases were divided into three groups as impartially as possible. First the patients were matched as closely as possible with respect to age, sex, and the various factors considered under the "natural handicap" including the many groups described before. From those nearest alike and having approximately the same "handicap," groups of 3 were chosen. Each group of 3 was arranged in three main columns according to the first letter of their names. Those having the highest letter of the alphabet were to receive daily, in addition to the general hospital diet, 500 cc. of a synthetic orange flavored preparation to which was added an amount of crystalline vitamin C equivalent to the amount of vitamin C in the same volume of fresh orange juice. Those next highest in the alphabet were to receive daily, in addition to the general hospital diet, 500 cc. of freshly prepared orange juice. Those having the lowest letter in the alphabet were to receive daily, in addition to the general hospital diet, 500 cc. of the synthetic orange flavored preparation without vitamin C. This was to constitute the control group.

The 102 patients were started on therapy in May 1935. In September 1935 it was necessary to add 17 patients to replace those who had died or been discharged from the sanatorium. Those who were thus rejected were patients who did not receive any treatment at all. Only 98 were finally carried into the experiment, of which 60 remained to the end. There were 34 controls in the beginning with 14 remaining to the end; 33 in the orange group, 23 of which remained to the end; and 31 in the vitamin group, with 23 remaining to the end. The heavy casualties in the control group before the experiments passed the six months period is significant.

Of the rejected cases, 11 for each of the orange and vitamin and 20 for the controls, 6, 5 and 6 respectively were rejected because of interference such as going home, the institution of some other treatment, death, or other events that caused a termination of the case before three months had elapsed. This type of "casualty" was about equal in all three groups.

The remaining cases of 5, 6 and 14 respectively were followed for more than three months. Most of them were discontinued before six months. A few were

carried longer, but because of some failure to get all the studies performed or some interference in the form of special diets they were rejected.

Of the 5 cases of the vitamin group, 2 were on the favorable side and 3 unfavorable, in 2 of which death occurred. Of the orange group there was one on the favorable side and 5 unfavorable, with three deaths. For the controls there were only 2 favorable against 12 unfavorable results, with seven deaths. Of the results on rejected cases of the three mass experiments, 51 per cent of the controls were unfavorable with 31 per cent deaths. The vitamin had 28 per cent unfavorable with 21 per cent deaths, and the orange group 31 per cent unfavorable with 21 per cent deaths.

The cases that were carried on into the experiment were then compared by every available means.

RESULTS OF TREATMENT

In analyzing the charts at the end of the experiment there is so much similarity of the three groups that they are practically interchangeable. While there was a greater number of cases in the orange and vitamin groups showing a favorable hematinic effect, as shown in the first report,² the average loss or gain was not sufficient to record by any laboratory means over the whole course of treatment.

An empirical method of calculation revealed also that there was little change roentgenologically between the composite figures of the three groups.

As to the clinical results, the weight gain or loss is the only factor that gives any precise information that can be tabulated. The patients remaining to the end who were not molested in some way by treatment or other interferences were compared in the table.

Of 23 patients remaining on orange, 10 (43.4 per cent) gained weight, 2 (8.7 per cent) were stationary and 11 (47.9 per cent) lost. In the vitamin group only 7 (30.4 per cent) gained; 9 (39.2 per cent) were stationary and 7 (30.4 per cent) lost. The controls had 4 (28.5 per cent) gain, 4 (28.5 per cent) stationary, and 6 (42.0 per cent) lost, respectively. The net result from this particular analysis reveals a similarity of all three groups.

THE SECOND MASS THERAPEUTIC EXPERIMENT

As stated previously, two more mass experiments were carried out in slightly earlier cases than the ones just described. In the second, there were 80 cases compared with 39 (12 controls, 13 orange and 14 vitamin) followed more than one year. There was no essential difference, however, in the final result. A sample chart of the second mass experiment is shown. The results may be interpreted as follows: In the controls the levels revealed saturation in most of the cases, but a few dropped to "unsaturation" levels. In most of the orange and vitamin groups there was a recovery in the urine of a maximum of about 200 mg. a day at the beginning, but the level usually dropped to about 150 mg. by six weeks. Counting 280 mg. a day intake with 20 mg. lost in sweat, feces and sputum, it leaves a consumption of from 60 to 150 mg. a day. A few very ill patients had a high value of only 150 mg. in the urine and a gradual drop to 120 or less as the winter came on, making a consumption of 110 mg. at the beginning and rising to 140 mg. at the end of the test period. This reveals that severe cases require approximately 150 mg. or more a day to care for their needs (chart 3).

A tremendous amount of research has been conducted to evaluate the relative effects of atmospheric environments on water balance or dehydration of the body. Whether one is treating patients for diseases or is managing workers, these statements hold true, since the heat loss is based on physical laws which have already been described.

As previously pointed out, extensive research has shown that definite physiologic reactions follow the effective temperature index rather than the dry bulb temperature. This fact should be important in the treatment of many human illnesses in which temperature derangement is encountered. As an example, Simpson⁶ has shown that induced fever therapy will give a rise in body temperature to 105 F. in from forty minutes to an hour with a dry bulb temperature ranging from 130 to 150 F. and a relative humidity from 35 to 50 per cent. However, Houghten, Ferderber and Gutberlet⁷ have shown that in a saturated atmosphere the

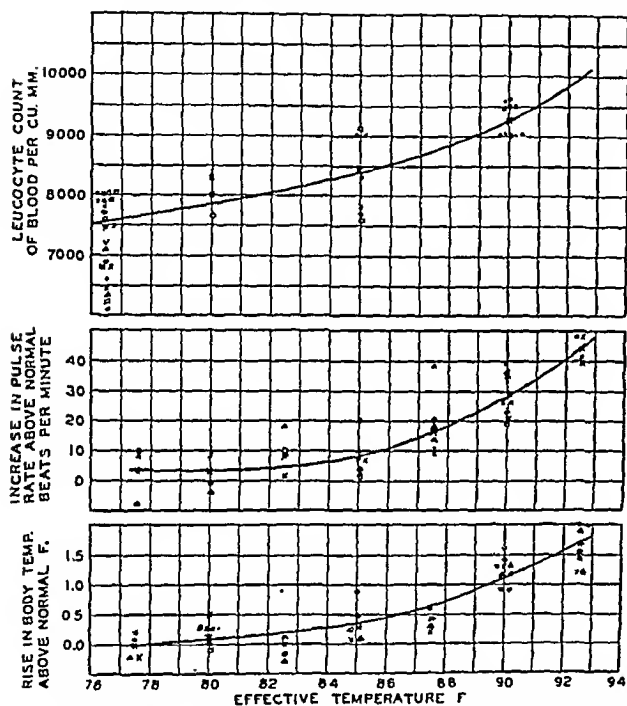

Chart 2.—Relation between the rise in body temperature, the increase in pulse rate, the change in the leukocyte count from normal during three hours' exposure and the effective temperature of the air condition.

same rise in body temperature will occur in about the same time with a dry bulb at approximately 113 F. There are no arguments offered here in favor of either high temperature and low humidity or relatively low temperature and high humidity in obtaining the desired end, but it should be obvious that with this wide difference in results, depending on the moisture content of the air, a greater appreciation of these facts should be of value in the field of medicine.

Research during recent years by us has also served to show very wide differences in the mode of heat losses depending on the moisture content of the air.⁸ In this connection we would point out that the human body

loses heat essentially by contact with the air; that is, the air in contact with the human body absorbs heat and moves away, allowing cooler air to come in contact with the body. This is known as sensible heat loss. At the same time, dry air in contact with the human body, particularly when it is bathed in perspiration, evaporates moisture from the surface and thereby removes heat equal to the latent heat of evaporation of perspiration removed, or 575 large calories per gram. This is recognized as latent heat loss.

A normal-sized man 68 inches tall (173 cm.), weighing 150 pounds (68 Kg.) seated at rest normally clothed dissipates about 100.8 large calories (400 British thermal units) of heat per hour without much variation for all temperatures above 60 to 70 F. The division of these calories between sensible and latent depends on the moisture content and the temperature of the atmosphere. For example, at 65 F. effective temperature, which is reasonably comfortable for a person normally clothed and seated at rest in winter, this person dissipates a total of 100.8 large calories per hour. About three fourths of this is sensible and one fourth latent, while for an effective temperature of 75 F., which is slightly warm for a summer conditioned space, approximately 67.5 per cent of the total heat is sensible and 32.5 per cent is latent. At 85 F. effective temperature, which represents a very warm but not unbearable condition, he loses the same amount of heat, of which 42.5 per cent is sensible and 57.5 per cent is latent. If the dry bulb temperature is equal to the body temperature, the entire amount of heat dissipated is latent. The foregoing values are subject to some variation, depending on the relative humidity of the air. This variation for most conditions is not great. A better division of these values is given by Houghten and others.⁹

From a practical standpoint this application may well be utilized in measuring the effects on workers in industry in which all gradations of the temperature range may occur. The physiologic effects of high effective temperatures can be well illustrated by the increases in pulse rates, elevations of body temperatures and, lastly, a rise in leukocyte count of the blood.¹⁰ Since we have shown that a rise in body temperature is a function of effective temperature, it is only natural that the pulse rate should follow the body rise. However, psychic stimuli definitely play a great part in changes in heart rate but can be disregarded after a period of adjustment to the hot environmental conditions. The change in leukocyte count may be more difficult to evaluate, since this observation was made incidental to the other data. Additional investigations by the authors show the rise in white cell count to be consistent in laboratory observations over the past two years, although no specific explanation is offered. Since much of this information was collected under conditions which might simulate certain unusual occupations, one could conclude that the physiologic changes may be caused by environment. It was observed in investigations on fever therapy by this department that frequent exposures to heat at short intervals produced a state of resistance to the heat itself and was accompanied by

failure of leukocytosis at the same time.¹¹ While this holds true for certain chronic illnesses, a vague possibility exists that there is a connection between continued exposures to excessively hot atmospheres over a long period of time and resistance to infection.¹²

At an approximate effective temperature of 85 F., the changes in body temperature, pulse rate and leukocyte count become noticeable, so that an effective temperature between 92 and 94 F. the differences in these three physical readings from normal are rather extensive. It must be remembered that these changes occur in laboratory subjects performing light work standing whose metabolic output amounts to 76 calories per square meter per hour. One could conclude that, had these subjects been seated at rest, the physiologic changes would have been less significant or, had they been performing heavy work of about 150 calories per square meter per hour, the changes would have been greater. This is offered as a measure for evaluating the exposure time in new processes of manufacture, so that the medical managers have some definite conception of what changes occur in the body of the industrial worker.

We offer no definite point at which conditions may be considered unsafe, since this is purely experimental, and its application may be of some value in our vast industrial life¹³ (chart 2).

There is some indication that at different seasons of the year physiologic reactions may vary according to the same effective temperatures. In a recently published paper¹⁴ this is clearly indicated to be between 81 and 90 F. effective temperature; but in excessively hot atmospheres of approximately 92 F. effective temperature or higher the physiologic changes are the same, irrespective of the season of the year. We have called this circumstance "acclimatization," indicating that the physiologic responses become adjusted to environmental temperatures.

Since the use of air conditioning has been more critically evaluated, its application to human comfort will interest the physician irrespective of locality. It is desirable to know the optimum comfort in winter heating or summer cooling in different geographic locations, so that some conclusions could be drawn as to the proper conditions for comfortable living in certain regions.¹⁵ These desires are interpreted in chart 3, in which occupants of certain spaces indicated their wishes regarding the comfort or discomfort of the conditions, all of which was plotted against the effective temperature in each location.

A rather interesting outcome of these collected data was the choice of the proper effective temperature

to be used in an experimental operating and recovery room at the Elizabeth Steel Magee Hospital,¹⁶ associated with the University of Pittsburgh. Of the many theories that have been advanced regarding the differences between inside and outside temperatures, we felt that an average of the comfort requirements in various localities would furnish some idea of the proper conditions. An effective temperature between 67 and 70 F. was chosen and the variation from these conditions was so slight that 80 per cent of the operating room personnel voted "comfortable," which coincided with the choice of office workers in other portions of the country. Apparently the surgeons desired a slightly cooler environment, owing perhaps to working while standing, the type of effort involved, heavier clothing and possibly mental stress. On the other hand, the office worker is usually seated, performs lighter work and wears less clothing. This does not mean, however, that the environ-

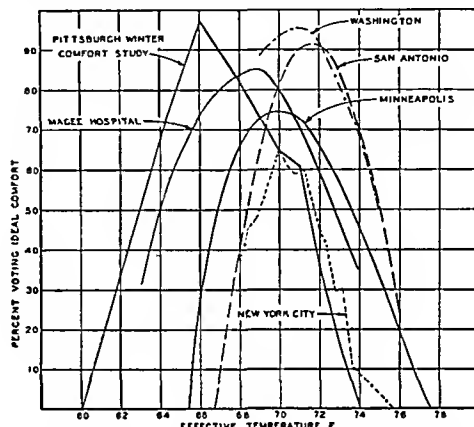

Chart 3.—Relation between effective temperature and percentage of persons indicating ideal comfort in various localities as indicated on graph.

ment of the office workers is comfortable for the surgeon, but it does furnish a basis for scientific investigation of what the optimum environmental conditions might be.

ABSTRACT OF DISCUSSION

DR. W. J. McCONNELL, New York: The authors have evaluated in the order of their importance the various physical factors of the air which determine in large measure the sensation of bodily comfort. Too much dependence cannot be placed on the dry bulb temperature. It is like reading the time by one hand of the clock. It gives considerable information but not complete information. In order to express similar sensations of comfort produced by thermally equivalent air conditions, the term "effective temperature index" was coined and need not be confusing if we remember first that effective temperature in reality is not a temperature at all, but merely a relative index of the temper of atmospheric conditions felt by the human body in response to the physical factors of the air. The scale is merely superimposed on the standard psychrometric chart. Second, we must consider that radiant heat is not included in the effective temperature. Where radiant heat sources prevail, they must be taken into consideration separately. Third, the index is based on saturation temperature; therefore the effective temperature index is usually lower than air temperature. Now, in order to improve that condition there is available a chart which has been revised on a 50 per cent relative humidity, so that the so-called comfort line is indicated by 70 rather than 66 and perhaps is better understandable by the majority of people who are accustomed to using the dry bulb temperature as an index for comfort.

LEUKOPENIA

A DISCUSSION OF ITS VARIOUS MODES OF PRODUCTION

JOHN S. LAWRENCE, M.D.

ROCHESTER, N. Y.

It has seemed to me that the average clinician spends little time in considering what physiologic mechanism may be at fault in patients who have leukopenia. One is prone to explain the condition on the basis of some abnormality in production of white blood cells by the hemopoietic tissue. While it is true that leukopenia is due in many instances to the failure of the blood-forming tissues to manufacture normal numbers of white blood cells, yet there are at least four other major mechanisms which may result in this condition. My purpose in making this presentation is to call attention to these additional conditions in the hope that all physicians may put more thought on leukopenia. With this in mind I present the following possibilities which I feel may take part in the development of leukopenia:

1. Diminished manufacture of white blood cells. This may be the result of (1) simple inhibition, (2) maturation arrest, (3) aplasia of the bone marrow and (4) infiltration of the bone marrow with foreign cells.
2. Increased elimination of white blood cells. Theoretically, this may occur when large quantities of cells are poured into an infected area such as an empyema or when large numbers of cells are lost through normal channels such as the gastrointestinal tract, the lungs, the spleen or the liver.
3. Increased rate of destruction in the peripheral blood due either to abnormal white blood cells or to abnormal substances in the blood channels which cause destruction of the white blood cells.
4. Redistribution of the white blood cells in the vascular channels, such as occurs with foreign proteins.
5. Redistribution of the white blood cells in the body as a whole, as is seen at times in leukopenic phases of leukemia.

DIMINISHED MANUFACTURE OF WHITE BLOOD CELLS

With regard to diminished manufacture of white blood cells, this may occur under the following conditions:

1. *Simple Inhibition.*—Such is thought to occur in many of the virus infections, typhoid, malaria and overwhelming infections. No satisfactory study has yet been made of these disorders in relation to the cause of leukopenia, and it is probable that other mechanisms, such as peripheral destruction, are at fault. The fact that a "shift to the left" is frequently present suggests that increased destruction or elimination may be factors also.

2. *Maturation Arrest.*—This is a term which was first proposed by Fitz-Hugh and Krumbhaar.¹ These investigators called attention to the fact that extreme leukopenia occurred at times in acute agranulocytosis of the Schultz type when aplasia of the granulocytic elements of the bone marrow was not present but, on the other hand, when myeloblasts or myelocytes or both were present in normal or increased numbers in

the bone marrow. An analogy was drawn between this situation and that existing in primary anemia in which large numbers of parent red blood cells were to be found in the bone marrow in the presence of few adult red blood cells in the peripheral blood. According to Fitz-Hugh and Krumbhaar,¹ the leukopenia in cases of acute agranulocytosis presenting normal numbers of parent white blood cells in the hemopoietic tissues was due to maturation arrest or failure of the white blood cell progenitors to mature into late myeloid forms. Plum,² in a discussion of this entire subject, has pointed out that in the majority of instances acute agranulocytosis is associated with aplasia of the granulocytic elements of the bone marrow. However, he has shown that in an appreciable number of instances this disease may occur in the presence of pathologic changes of the type reported by Fitz-Hugh and Krumbhaar.¹ The fact has been stressed that there is unanimity of opinion as to

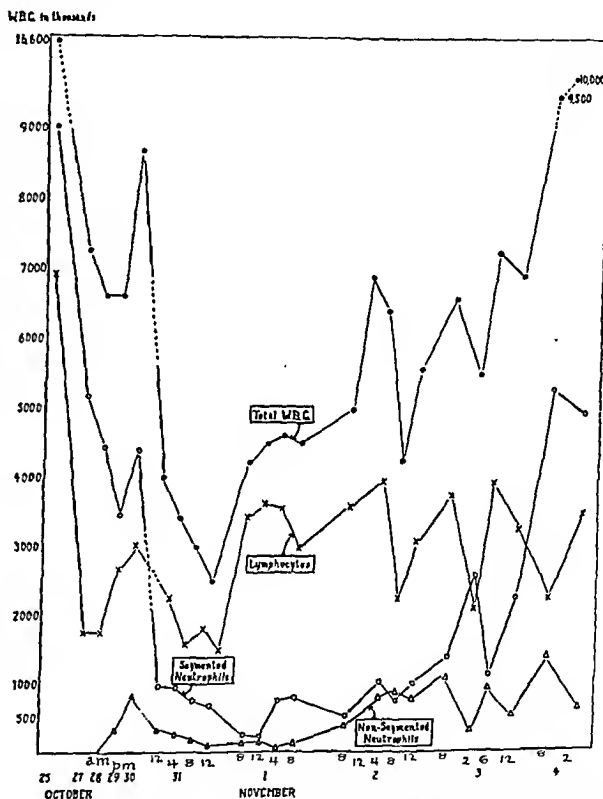

Fig. 1.—Variations in the white blood cells of a cat before the height of the disease, at the height of the disease and during the first days of recovery. Note the tremendous diminution in the neutrophils at the height of the disease and the increase in the stab forms just before the height of the disease and particularly during recovery. The lymphocytes are depressed, but not so markedly.

the absence of differentiation of the myeloid cells of the bone marrow in the active stages of the disease. According to Plum,² the differences in the condition of the bone marrow are to be explained by the different stages of the disease at which the bone marrow has been removed. He has postulated three stages of the disease as regards the bone marrow: one in which the bone marrow is poor in cells; another when the marrow is rich in cells or, in other words, when regeneration has begun but has not advanced to the stage of differentiation into late myeloid forms, and a third when the marrow picture is normal, which is to be found in patients who die from complications subsequent to

The expenses of this work were defrayed in part by a grant from the John and Mary R. Markle Foundation.

Read before the Section on Practice of Medicine at the Ninety-First Annual Session of the American Medical Association, New York, June 13, 1940.

hematologic recovery. Rohr³ had presented his observations previously which were consistent with Plum's ideas in this regard. My associates and I⁴ have shown

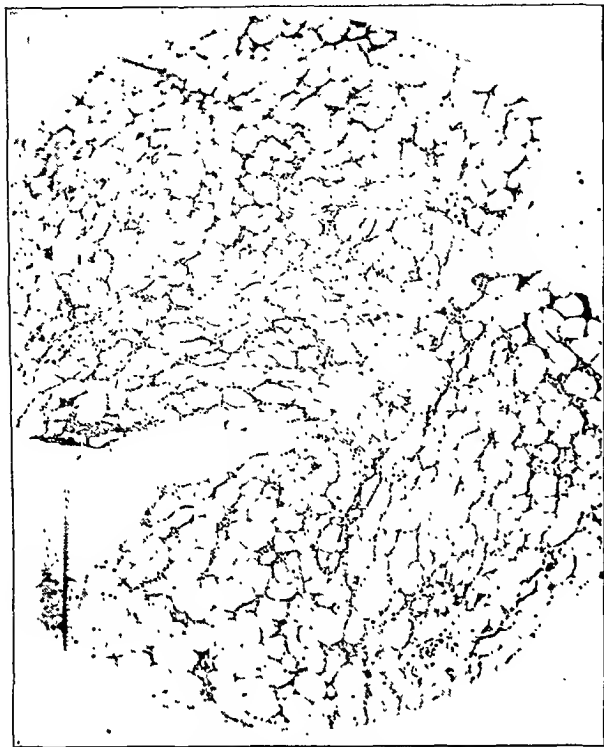

Fig. 2.—Section of bone marrow from femur of cat 279 at the height of the disease. Note the hypoplasia. Reduced from a photomicrograph with a magnification of 100 diameters.

recently that very rapid changes may occur in the bone marrow of cats with a disease which closely simulates the human disorder and to which we have given the name "infectious feline agranulocytosis." This disease was shown to be due to a virus or filtrable agent and was characterized by the development of leukopenia and pronounced neutropenia on the sixth to the ninth day after exposure to the infectious agent. There was no anemia of any note. Figure 1 shows the changes which occur in the white blood cells in a typical animal with this disease.

The pathologic changes were limited almost entirely to the bone marrow, lymph nodes, spleen and intestine. The changes in the lymph nodes and spleen were principally those due to proliferation of the reticuloendothelial cells. Intranuclear inclusion bodies were found in the epithelial cells of the gastrointestinal mucosa, in reticular cells of the lymphoid tissue and in the alveolar epithelium of the bronchial mucous glands. In the bone marrow, the most striking change was in the granulocytic cells. These were in most instances reduced in total numbers, and in all instances there was absence of differentiation into late myeloid forms at the height of the disease. The erythroid cells remained in normal percentages, and the same was true for the megakaryocytes. If the animal recovered, the bone marrow showed a very sudden and dramatic transformation. Within twenty-four hours the total number of bone marrow cells increased a great deal and, along with this, there

was some differentiation into late myeloid forms. By the end of four days, the marrow had returned to an essentially normal picture. Figures 2, 3, 4, 5, 6 and 7 are typical areas of the bone marrow of one animal taken at the height of the disease and at twenty-four hours and seventy-two hours after recovery began. It will be seen from these illustrations that the bone marrow picture obtained in this disease varied a great deal, depending on the stage of the disease at which the specimen was obtained. If changes occur as rapidly in the bone marrow of the human disease as they do in that of the cat, it is easy to understand how various pictures may be ascribed to the bone marrow in the human disorder.

While it is conceded by all that maturation arrest and hypoplasia of the myeloid elements of the bone marrow probably represent the major processes involved in the development of neutropenia in cases of acute agranulocytosis, nevertheless it should be mentioned that, in the minds of some, these mechanisms do not explain the entire picture. Thus the sudden precipitous disappearance of neutrophils in patients sensitive to aminopyrine is difficult to explain on this basis, since the neutrophils may disappear from the peripheral blood within a few hours after the ingestion of aminopyrine. Fitz-Hugh⁵ has suggested that peripheral destruction of the white blood cells may account for this part of the reaction in man. Recent studies at the University of Rochester point rather strongly to peripheral destruction being an important factor in "infectious feline agranulocytosis." Cats with severe leukopenia have had about one third of their blood removed by cardiac puncture at the same time that an equivalent amount of blood from a normal cat was being given into the femoral vein. By this procedure it has been found impossible to elevate the white blood cell count of the

Fig. 3.—Same section shown in figure 2, slightly reduced from a photomicrograph with a magnification of 1,500 diameters. Note the absence of differentiation of the myeloid cells.

leukopenic animal for more than a very brief temporary period. In another experiment, an animal with only 50 white blood cells per cubic millimeter was joined to

a normal cat by means of the carotid arteries. Cross circulation was instituted and the animals lived for four hours. The total number of white blood cells was increased in the diseased animal to values comparable

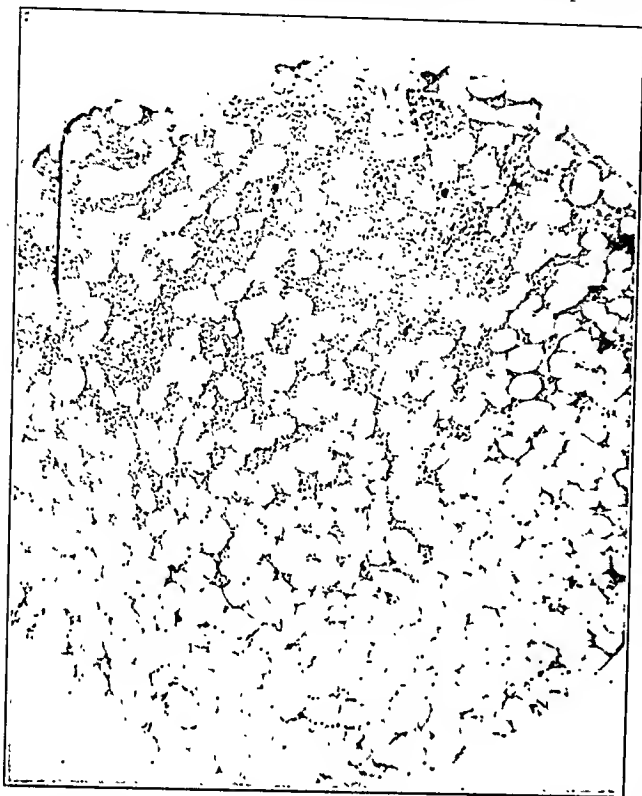

Fig. 4.—Section of bone marrow from femur of cat 279 on first day of recovery. The total number of cells has increased materially. Reduced from a photomicrograph with a magnification of 100 diameters.

with those for the normal animal, but there was a decided increase in early or "stab" forms, indicating that the bone marrow of the normal cat was being forced to work hard in order to keep the cells up to this level. A similar experiment with two normal cats did not result in any "shift to the left" during a period of twelve hours.

The following case is illustrative of leukopenia due to acute agranulocytosis:

CASE 1.—A. K., a white woman aged 76, a widow, was admitted to the Rochester Municipal Hospital April 12, 1935. The pathologic changes of interest were moderate pyrexia associated with a diffusely red throat and infection of the gums. She had a white blood cell count of 1,420 per cubic millimeter, all of which cells were lymphocytes. The red blood cell count was 3,500,000 per cubic millimeter, and the hemoglobin was 10.2 Gm. per hundred cubic centimeters. She died on the fourth day after admission, her white blood cell count having dropped in the interim to 200 per cubic millimeter. No neutrophils were found. The bone marrow of this patient showed moderate depletion of myeloid cells, all of which were of an early undifferentiated type. Red cell progenitors were in normal abundance. Figure 8 shows a typical area from a stained section of this bone marrow.

3. *Aplasia of the Bone Marrow.*—Not many cases of true pathologic aplasia of the bone marrow are encountered, since most patients with so-called aplasia of the bone marrow have merely functional aplasia, as pointed out by Thompson and his associates.⁶ As representa-

tive of true aplasia of the bone marrow may be mentioned the following case:

CASE 2.—F. G., a white man aged 56, married, was admitted to the Strong Memorial Hospital May 29, 1931 with the following blood picture: red blood cells 1,270,000 per cubic millimeter, hemoglobin 3.5 Gm. per hundred cubic centimeters, white blood cell count 3,600 per cubic millimeter. The differential white blood cell count was neutrophils 38 per cent, lymphocytes 58 per cent and monocytes 4 per cent. One normoblast was found in the blood smear. Platelets were practically absent from the blood smear. The patient died July 24, at which time the white blood cell count was 1,600 per cubic millimeter. The bone marrow showed marked depletion of cells of all types. Figure 9 represents a typical area from a stained section of the vertebral bone marrow of this patient.

4. *Infiltration of the Bone Marrow.*—This usually results in an increased number of white blood cells in the peripheral blood, but in exceptional instances, when the infiltration is marked, leukopenia may result.

INCREASED ELIMINATION OF WHITE BLOOD CELLS

A clear-cut illustration of this mechanism is not easy but theoretically it is a distinct possibility. In cases of severe infection, leukopenia occasionally results. The usual explanation of this is that the toxin or toxins elaborated suppress the bone marrow. However, there is no positive evidence that the leukopenia is due to this, and it may be that it results from massive loss of cells. The following case may be used for purposes of discussing this mechanism:

CASE 3.—E. J., a white woman aged 44, married, admitted to the Strong Memorial Hospital Dec. 26, 1934, had had diarrhea for four weeks and had a typical course of ulcerative colitis. Her white blood cell count was 2,050 per cubic millimeter and the differential picture was as follows: myelocytes 1 per cent, juveniles 7 per cent, stab cells 32 per cent, segmented cells 44 per cent, lymphocytes 16 per cent. At autopsy, multiple ulcers of the large intestine were found with acute inflammation and necrosis and multiple perforations of the cecum. The bone marrow showed large numbers of cells of

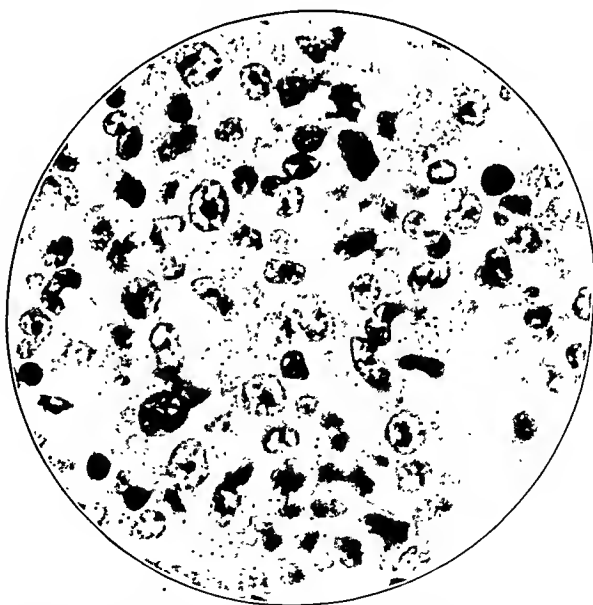

Fig. 5.—Same section shown in figure 4, slightly reduced from a photomicrograph with a magnification of 1,500 diameters. Note that differentiation of myeloid cells into stab forms is seen to have begun.

all types. There was a moderate increase in the number of eosinophils. The erythroid cells appeared normal. The myeloid cells were present in large numbers and showed good differentiation into adult forms. The megakaryocytes were normal.

6. Thompson, W. P.; Richter, M. N., and Edsall, Katherine S.: An Analysis of So-Called Aplastic Anemia, *Am. J. M. Sc.* 187:1 (Jan.) 1935.

It is obvious that several factors may have been responsible for the leukopenia. For example, poor absorption from the gastrointestinal tract, deficient food intake, elaboration of a leukotoxic substance and loss of white blood cells into the gastrointestinal tract or the peritoneal cavity or both should all be considered with reference to the leukopenia. However, we have had a few other cases of infection of the bowel associated with leukopenia, and it seems at least possible that the leukopenia may be due in part to increased elimination of white blood cells. Certainly the appearance of the bone marrow in this case points to satisfactory manufacture of these cells.

INCREASED RATE OF DESTRUCTION IN THE PERIPHERAL BLOOD

This could be due either to abnormality of the white blood cells or to abnormal substances in the blood

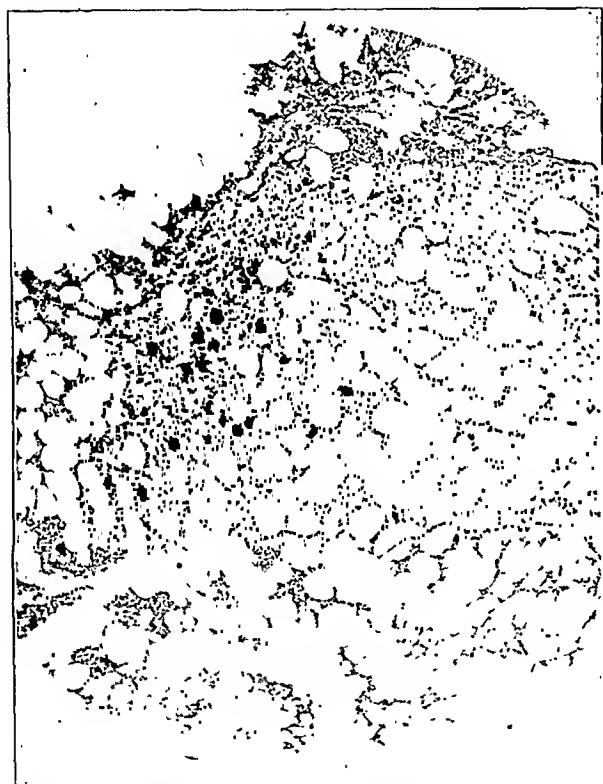

Fig. 6.—Section of bone marrow from humerus of cat 279 on the third day of recovery. Reduced from a photomicrograph with a magnification of 100 diameters.

plasma. I feel confident that both conditions exist at times. The following unusual case may be taken as illustrative of probable increased rate of destruction in the peripheral blood:

CASE 4.—W. G., a white woman aged 60, unmarried, has been seen in the Rochester Municipal Hospital on repeated occasions since 1928, the last admission being on Jan. 1, 1940. In 1928 she was found to have a white blood cell count of from 600 to 1,300 per cubic millimeter. On each of her admissions since then she has been found to have a pronounced leukopenia. Her admission in October 1939 was occasioned by excessive bleeding associated with thrombopenia, which she had not had previously. The differential count at this time was eosinophils 6 per cent, myeloblasts 1 per cent, myelocytes 10 per cent, juveniles 19 per cent, stab cells 7 per cent, segmented cells 11 per cent, lymphocytes 31 per cent, monocytes 10 per cent, degenerated cells 4 per cent, unclassified 1 per cent. The

total white blood cell count was 1,700 per cubic millimeter. A specimen of sternal bone marrow revealed conditions within normal limits. In view of this and of the fact that this woman

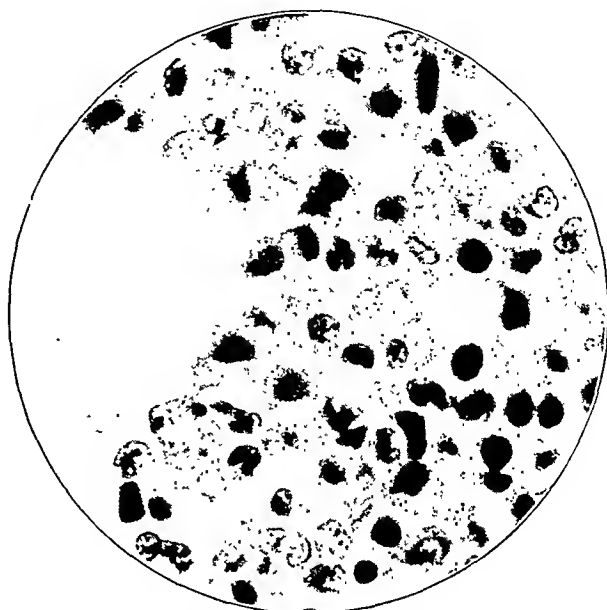

Fig. 7.—Same section shown in figure 6, slightly reduced from a photomicrograph with a magnification of 1,500 diameters. Note that normal differentiation of the myeloid cells was found.

had had severe leukopenia over a period of twelve years without any story of repeated or severe infections, it was felt that she probably was manufacturing a normal number of white

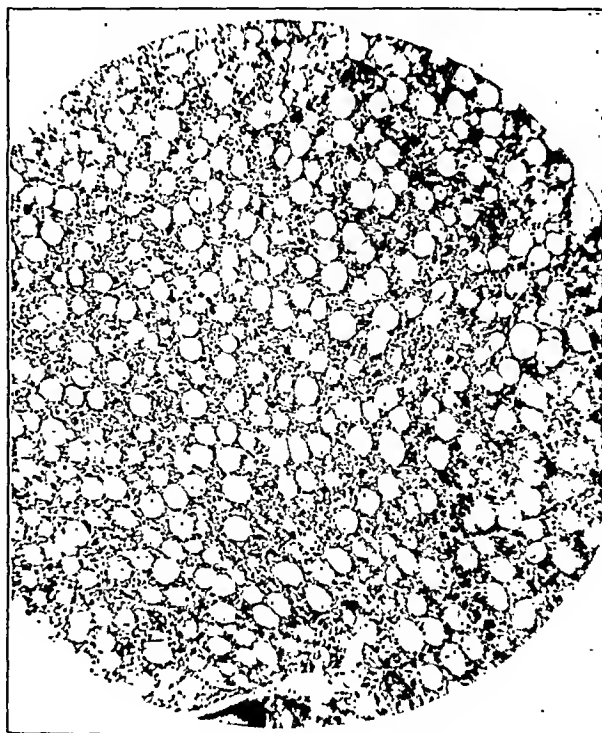

Fig. 8 (case 1).—Bone marrow in human acute agranulocytosis. Section of the vertebral bone marrow, reduced from a photomicrograph with a magnification of 100 diameters. Under high magnification, absence of differentiation of the myeloid cells was found.

blood cells. Her main difficulty seemed to be due to thrombopenia. Accordingly, it was decided to remove her spleen. This was done on January 22. Five hours after splenectomy she

had 13,000 white blood cells per cubic millimeter, and the differential count was juveniles 1 per cent, stab cells 34 per cent, segmented cells 53 per cent, lymphocytes 3 per cent, monocytes 7 per cent, degenerated cells 2 per cent. The white blood cell count gradually returned to its low level. She made an uneventful recovery and left the hospital free from hemorrhagic tendencies.

While the postoperative rise in white blood cells was not as severe as usual, it was appreciable, particularly since the normal level for this woman was low. This demonstrates that she was able, under the proper stimulus, to produce white blood cells in large numbers. The fact that she has gone so long with the leukopenia and without having any more trouble with infections than is customary for the normal adult makes me believe that she may have been manufacturing normal numbers of white blood cells. Of course this view is hypothetical and not proved.

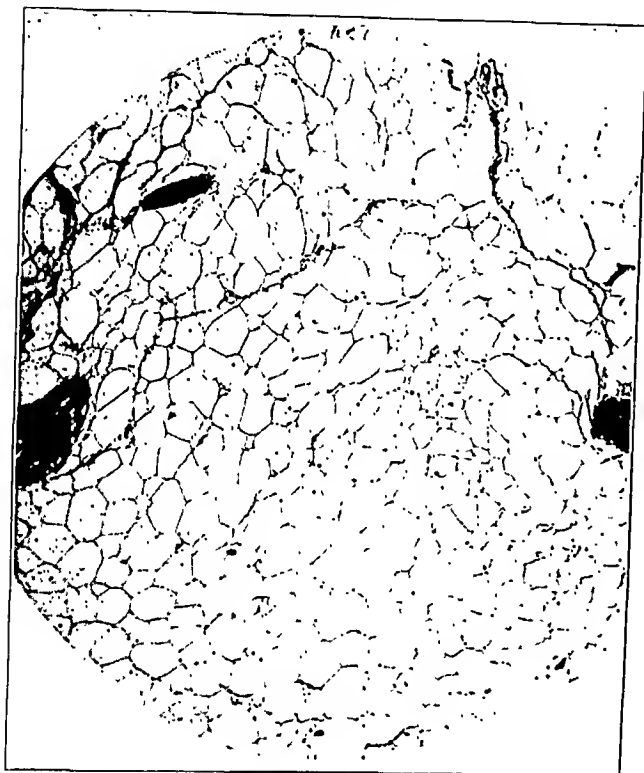

Fig. 9 (case 2).—Bone marrow in true aplastic anemia. Section of the vertebral marrow, reduced from a photomicrograph with a magnification of 100 diameters. Note the almost complete absence of cells of all types.

That white blood cells may be destroyed in large numbers in the peripheral blood has been shown conclusively by Chew, Stephens and Lawrence,⁷ who were able to cause the disappearance of all neutrophils from the peripheral blood of the guinea pig in three minutes by the intracardial injection of antineutrophilic serum. This antiserum was produced by repeated injections of large numbers of neutrophils of the guinea pig into the ear vein of rabbits. Figures 10 and 11 show the effect of antineutrophilic serum on the peripheral white blood cell picture of the guinea pig. It will be seen that the effect of this antiserum on the neutrophils persisted for from twenty-four to eighty-four hours. Study of sections made from various organs of the body failed to reveal any accumulation of these cells in them. Further, it was shown that neutrophils could not be called forth by infection or other agents that ordinarily produced

local accumulation of neutrophils in those animals which had been treated with antineutrophilic serum. For example, animals made leukopenic by the injection of this antiserum showed no accumulation of neutrophils

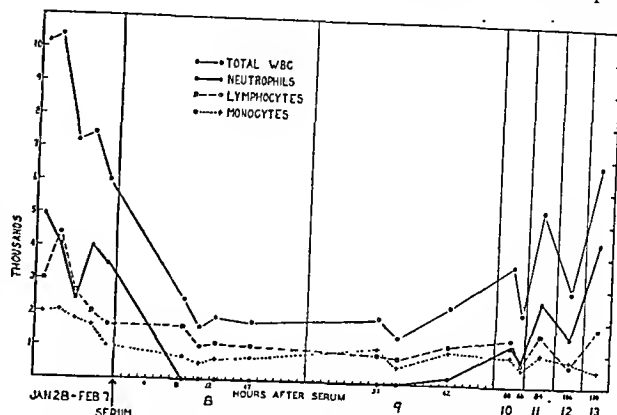

Fig. 10.—Effect of antineutrophilic serum on the peripheral white blood cell picture of the guinea pig. Note the decided drop in the number of neutrophils. These cells did not return to their normal level until eighty-four hours later.

in the subcutaneous tissue at the site of the injection of 0.1 cc. of a twenty-four hour broth culture of *Staphylococcus aureus* as contrasted with the local accumulation of large numbers of neutrophils in untreated healthy control animals when injected with the same amount of the broth culture. Recently, my associates and I have been able to show that, coincident with the peripheral leukopenia, there is a diminution in the

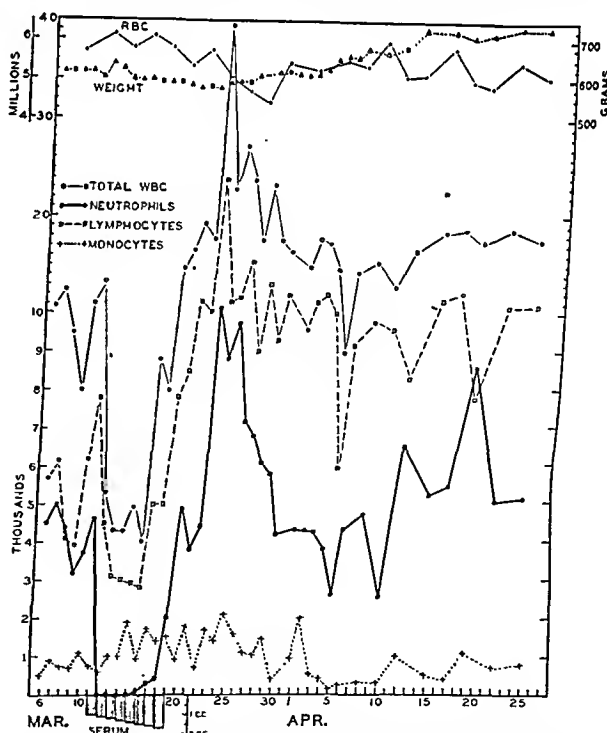

Fig. 11.—Effect of repeated injections of antineutrophilic serum on the peripheral white blood cell picture in the guinea pig. Note that the granulocytopenia was maintained for seven days and that there was a compensatory leukocytosis after this. The red blood cells were not affected.

number of white blood cells in the omental venules. This condition has been observed for three and one-half hours following intravenous injection and has been

7. Chew, W. B.; Stephens, D. J., and Lawrence, J. S.: Antileukocytic Serum, *J. Immunol.* 30: 301 (April) 1936.

demonstrated in animals from twelve to eighteen hours after the intraperitoneal injection of antineutrophilic serum. In these studies we opened the peritoneal cavity of the guinea pig and removed a part of the intact omentum. This has been placed on a warm stage and kept moist with physiologic solution of sodium chloride. The circulation has been observed then through a microscope and, in some instances moving pictures have been taken.

REDISTRIBUTION IN THE VASCULAR CHANNELS

This is a well known phenomenon and has been commented on often in physiologic literature. One of the most detailed discussions of this subject with which I am familiar is that by Vejens.⁸ Hydrophile colloids such as gelatin, globulin and fibrinogen are known to produce peripheral leukopenia and neutropenia when given intravenously. This response is thought to be due to the white blood cells, particularly the neutrophils, assuming a marginal position in the venules in certain of the internal organs, i. e. liver, spleen and

most conditions it functions well and maintains a normal ratio of cells in the vascular channels to those in the tissues. Occasionally this mechanism breaks down and one may find great numbers of cells in the tissues but only a few in the blood. The best illustration of this I know is in so-called aleukemic leukemia. In this condition there may be leukopenia and yet the various tissues in the body may be filled up with white blood cells. That this may occur in other conditions is a distinct possibility.

CONCLUSION

There are at least five different mechanisms which may be responsible for leukopenia. If more thought is given to leukopenia with reference to the mechanism which may be at fault, progress in its interpretation and handling will be enhanced.

260 Crittenden Boulevard.

ABSTRACT OF DISCUSSION

DR. RUSSELL L. HADEN, Cleveland: The problem of leukopenia from the clinical point of view concerns the polymorphonuclear cells almost entirely. For this reason the term granulopenia seems preferable. Few of us appreciate what is happening to the granular cells normally. Each cell lives only a short time—probably not over four days—so that five to ten billion new cells must be released from the marrow every day to make up for those destroyed. The number of granular cells which can be made by the marrow to supply normal needs is enormous. The granular cells have little function while in the circulation. Cells in a stained film of blood are en route from the marrow to the point of activity. Almost all the cases of granulopenia seen clinically belong to Dr. Lawrence's first group. In thinking of granular leukopenia one considers (1) whether the marrow tissue is deficient in quantity as it is in the leukopenia of aplastic anemia; (2) whether the marrow tissue is functioning normally; the function is qualitatively impaired with aminopyrine intoxication, so the cells do not mature normally; in the depression seen with Banti's disease there is a quantitative decrease in function, or (3) whether there is some mechanical barrier to the emergence of cells from the marrow. In leukopenic myeloid leukemia the hyperplastic marrow seems to keep the cells from leaving the marrow normally. Probably this mechanical factor plays a more important part in leukopenia than is ordinarily realized. In the last two years, we have studied in our hematology laboratory 22 cases in which the total white blood cell count was below 2,500. In 2 an infection and in 4 various drugs had produced leukopenia by depressing the marrow. In 13 cases, leukemia or other bone marrow disease was responsible for the leukopenia. I was unable to classify 3 cases as to etiology. I will review our cases again in the light of Dr. Lawrence's discussion and try to determine whether the other mechanisms responsible for producing leukopenia might be operative in our cases. It is possible, as he suggests, that the cells may be taken out of the circulation rapidly or be destroyed in the circulation. We are indebted to Dr. Lawrence for emphasizing the numerous ways in which leukopenia may be brought about.

DR. JOHN S. LAWRENCE, Rochester, N. Y.: We have found it impossible to increase, except temporarily, the white blood cell count of animals at the height of the disease by means of replacement of large amounts of diseased cats' blood by the blood of normal cats. Of course we recognize that this does not prove that the cells were destroyed. They may have been lodged in the blood vessels in various areas of the body. We are trying to prove this point, and one of the procedures that we are carrying out is the use of cross circulation between the normal animal and the animal that has, say, 50, 100 or 200 white blood cells in the peripheral blood. I think that by means of this we shall be able to answer the question. We have not done enough work in this connection to make any final statement, but, as far as it goes, it does indicate that in

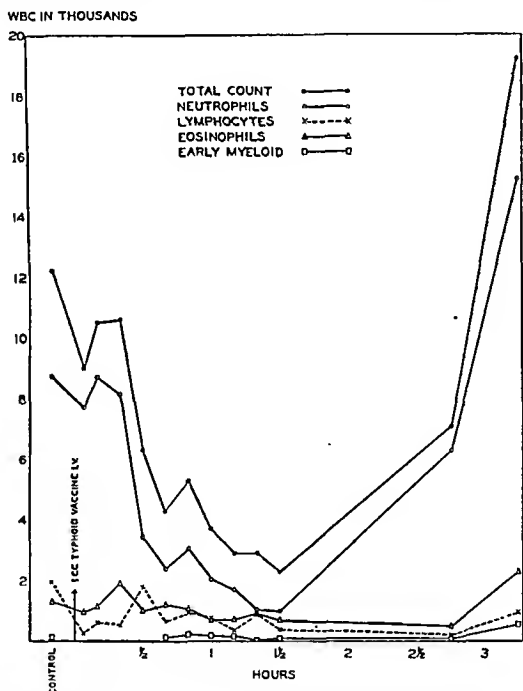

Fig. 12.—Effect of typhoid vaccine on the peripheral white blood cell picture of the cat; 1 cc. of typhoid vaccine was given intravenously.

omentum. This phenomenon can be readily observed under the microscope. My associates and I⁹ have recently shown kodachrome moving pictures of the omental circulation which illustrate this reaction very well. One of the best clinical illustrations of this is to be found following injection of typhoid vaccine intravenously in man. Figure 12 shows the changes in the peripheral blood of the cat following injection of typhoid vaccine intravenously.

REDISTRIBUTION IN THE BODY AS A WHOLE

The mechanism that is responsible for the distribution of the white blood cells between the tissues and the vascular channels is unknown. However, under

9. Lawrence, J. S.; Stringfellow, Margaret B.; Ackart, R. J.; Bishop, F. W., and Ariel, Irving: Infectious Feline Agranulocytosis: Kodachrome Moving Picture Demonstration of the Circulation of the Omentum as Affected by Serum from a Cat with This Disease, J. Clin. Investigation, to be published.

this particular disease (which is not a disease of man, however) there is peripheral destruction taking place, and that normal cells given to a diseased cat will be destroyed rapidly. I am not sure that I would agree entirely with Dr. Haden about placing almost all of the cases of leukopenia that we have in group I, since I feel that if more study is made of leukopenia we shall be able to place more and more patients with leukopenia in other groups.

THE USE OF BISMUTH COMPOUNDS IN SYPHILOTHERAPY

EDMUND N. WALSH, M.D.

WHITING, IND.

AND

S. WILLIAM BECKER, M.D.

CHICAGO

In the past twelve years the treatment of all types of syphilis at the University of Chicago Clinics has been planned with the use of much more bismuth than has usually been considered as standard or optimum treatment. In this report we wish to evaluate the results of such treatment of early syphilis, asymptomatic neurosyphilis and tabes dorsalis over a ten year period and compare these results, as far as possible, with corresponding data from the Cooperative Clinical Group studies.

PRESENT DAY STATUS OF BISMUTH IN SYPHILOTHERAPY

Since Sazerac and Levaditi¹ in 1921 first popularized bismuth as an antisyphilitic drug, it has gone through much the same cycle as was previously traversed by the roentgen ray and arsphenamine and as we have recently seen carried out with sulfanilamide. There was first a period of overoptimism, especially on the part of some members of the French school who hailed bismuth compounds as superior to the arsphenamines if not in initial potency certainly on the grounds of lesser toxicity. Many new bismuth preparations were offered for use with little or no investigation as to their efficacy or toxic effects. Reports soon began to appear of accidents in the course of treatment, intoxications, sometimes with fatal results, and later, evidence that the therapeutic efficiency of the drug was not nearly as great as was at first thought. The next portion of the cycle, in which we still find ourselves as far as bismuth is concerned, is that of careful experimental study and clinical trial which will eventually determine its place in the treatment of syphilis.

The present day knowledge of bismuth as an antisyphilitic drug can be briefly summarized. Bismuth will cure experimental syphilis in animals; it causes sterilization of surface lesions, reversal of the Wassermann reaction and cure as shown by lymph node transfers. "Cures" have been reported in a certain percentage of patients with early syphilis who were treated with bismuth compounds alone.² At the hôpital Cochin in Paris, bismuth has been used to the exclusion of the arsenicals in all types of syphilis since 1921 with what

the staff considers good results.³ On the other hand, there are reports of clinical and serologic relapses in patients while they were under bismuth therapy.⁴ In addition, the prophylactic use of bismuth, which at first seemed to offer such a potent weapon for the control of syphilis, has been condemned because it does not uniformly prevent infection.⁵ Thus bismuth alone, while sufficient in some instances, cannot be relied on to cure syphilis.

An enormous amount of work has been done, chiefly in this country, during the past fifteen years on the pharmacology of bismuth preparations (Cole and Sollmann, Hanzlik, Kolmer, Klander, Gruhitz). In general, the effectiveness of bismuth salts in syphilotherapy seems to be directly proportional to the amount of elemental bismuth which is available in an ionizable form in the body. This is dependent on the bismuth content of the compound, its physical properties (tissue solubility), the vehicle used and the amount administered. The spirocheticidal effect varies in different animals.⁶ There is also probably some difference in behavior between the electronegative and electropositive forms, especially as regards penetration of the nervous system.⁷ The recent work of Eagle⁸ suggests that the mode of action of bismuth in syphilotherapy is a direct spirocheticidal effect rather than a secondary effect through the formation of a protein-bismuth complex, bismoxyl, postulated by Levaditi.⁹

A large part of the experimental work deals with absorption, excretion and toxicity of the various bismuth preparations. It was found early that bismuth compounds given intravenously were highly toxic and could not safely be used therapeutically.¹⁰ The literally hundreds of compounds that have been advocated for intramuscular use can be classified roughly as follows: (1) tissue soluble, (2) water soluble, (3) water soluble suspended in oil, (4) oil soluble in oil and (5) insoluble suspended in oil. Their tissue solubility, which determines the rate of absorption, decreases in the order in which they are listed. The tissue-soluble salts are rapidly absorbed to give a relatively transient high concentration of bismuth in the blood as gaged by a rapid urinary excretion. The toxicity of these preparations is greater, and their chemotherapeutic index in some cases may be as low as one.⁶

On the other hand, the insoluble salts suspended in oil are absorbed very slowly, and with repeated doses there is a cumulative effect. The therapeutic index of these preparations may be as high as 166.⁶ A certain variable proportion of the bismuth introduced into the body is not excreted at once but is retained by the various organs and eliminated gradually over a long period of time. This is exclusive of the bismuth depots which are formed at the sites of injection when any but the

tissue-soluble salts are used. The greater portion of bismuth is excreted through the kidney and the remainder through the bowel. The relative proportion varies considerably with the preparation used but in general is about 9 to 1. All investigators have found essentially the same percentage distribution of the stored bismuth in the organs and tissues. Listed in order of decreasing percentage content, they are kidney, liver, bile, spleen, ileum, colon, lung, jejunum, brain and blood. The actual amount of bismuth in any one organ depends on the dosage, but the relative distribution is independent of the amount given.

As might be expected, since approximately 90 per cent is excreted through the kidney and since this organ shows the highest concentration of bismuth, it is the first to show toxic effects in the experimental administration of bismuth. According to Kolmer⁶ the injury is primarily and essentially a nephrosis with maximum changes in the convoluted tubules. The pathologic changes are the same regardless of the type of compound used, and thus probably are caused by the bismuth itself. Recent autopsy studies¹¹ have been made on 15 patients who received intramuscular bismuth therapy. In 2 there was evidence that renal damage due to bismuth probably contributed to the patients' death. However, renal damage did not seem to be proportional to the concentration of bismuth in the kidney.

COMPLICATIONS FROM BISMUTH THERAPY

The complications occurring during treatment that have been attributed to bismuth are many but fortunately the majority are of little real importance. Beerman¹² collected twenty-three deaths from the administration of bismuth recorded in the literature up to 1932. Of these six followed intravenous administration or were due to embolism subsequent to accidental intravenous injection. Seventeen deaths were due to delayed toxic effects which included acute yellow atrophy of the liver, stomatitis, nephritis, hemorrhagic phenomena and granulocytopenia. Vigne¹³ listed the relative frequency of intolerance to bismuth in 202 of 2,390 patients as follows: stomatitis, 72 per cent; bismuth grip, 10 per cent; local pain, 9 per cent; abscess, 3.3 per cent; cutaneous eruptions, 5 per cent; all other, 6 per cent.

These proportions would vary considerably depending on the type of patient, technic of administration and the preparation used. The most common are oral complications varying from the well known blue line to ulceration. The frequency of actual stomatitis has been found to be inversely proportional to the quality of the oral hygiene of the patient.¹⁴

Some degree of local pain at the site of injection is about as frequently complained of as the blue line on the gums but it is seldom severe. In many patients there develop localized areas of induration in the gluteal muscles where the injections are usually given. These are in most cases only mildly tender. Formation of abscesses and localized embolism from accidental intra-arterial injection are relatively rare, although a considerable number of cases have been reported.¹⁵

The cutaneous manifestations of bismuth "hypersensitiveness" most commonly take the form of a mildly exudative pityriasis rosea-like eruption. Herpes zoster, exfoliative dermatitis and hemorrhagic, urticarial and erythema multiforme-like lesions have also been attributed to bismuth.¹⁶ Jaundice at times has apparently been caused by the drug.¹⁷ However, after jaundice and most of the cutaneous eruptions the drug may be resumed without a recurrence of the complication.

Most reactions to bismuth therapy are avoidable. Proper oral hygiene, careful injection technic followed by massage over the site of injection and regular examination of the urine would eliminate a high percentage of bismuth accidents and complications.

COMBINED TREATMENT WITH THE ARSPHENAMINES AND BISMUTH COMPOUNDS

A combined treatment of syphilis with the arsphenamines and bismuth was, of course, considered and tried soon after bismuth was found to be of use in syphilotherapy. For the most part there were two directly opposed trends of thought on the subject: (1) Why risk giving the toxic arsenicals when bismuth will accomplish the same result with a sacrifice only of time? (French school) or (2) Why bother with a less effective drug like bismuth when the arsenicals will do the work more quickly and better? (German school). In general it was considered that the combined toxic effects of the two drugs would offset any advantage gained.

Wright¹⁸ in 1927 was one of the first in this country to advocate the simultaneous administration of bismuth and the arsphenamines. Schamberg¹⁹ urged the use of combined treatment, giving as the chief advantage that thereby the dosage of and the reactions caused by the arsphenamines could be reduced. Both authors reported satisfactory serologic and clinical results. Sézary²⁰ in 1930 stated, after nine years' experience, that mixed treatment gave better results, no increase in toxic effects and fewer neurorecurrences, and he had also noticed that when arsphenamine was given with bismuth fewer cases of stomatitis were seen.

Clausen, Tatum and Longly²¹ have recently found evidence working with experimental rabbit syphilis that provides a scientific basis for combined treatment. They found that whereas the therapeutic effects of fractional doses of the arsphenamines and bismuth given together are mathematically additive this does not hold true for their toxic effects. Thus, giving three quarters of the minimal curative dose of bismuth plus one quarter the minimal curative dose of an arsphenamine, or vice versa, will cure rabbit syphilis; giving these same proportions as applied to minimal lethal doses of the drugs does not cause death.

The system of treatment used in the University of Chicago Clinics was devised by one of us (S. W. B.) following a study of the various methods used for the treatment of early syphilis at the Mayo Clinic.

			176	28	81

tinuous administration of bismuth for the first forty to fifty weeks of treatment, (2) the short interval between all arsenical courses (never more than five weeks) and (3) the tapering off with four bismuth courses with increasing rest periods.

The 55 patients of whose treatment the results are summarized and compared with the Cooperative Clinical Group material (table 2) include all those who were under observation for over two years with an average observation time for the group of five years. There were 5 patients with seronegative primary, 9 with seropositive primary, 31 with early secondary, 6 with late secondary and 5 with early latent syphilis. Seven had had some previous treatment but of these all had positive blood reactions and 5 had active lesions when first seen.

Bismuth salicylate in oil was used intragluteally in all cases. In a few patients with secondary eruptions two to three preparatory injections of soluble bismuth were given before starting the regular schedule. Gruhitz,²³ Irgang²⁴ and more recently Kolmer⁶ found that bismuth salicylate in oil is probably the best tolerated of the bismuth preparations, yet because of its slow absorption, repeated doses keep the tissue concentration as judged by urinary excretion (2 to 4 mg. per day²⁵) at a therapeutic level over long periods of time.

The arsenical used must also be considered in evaluating the effect of bismuth in any course of combined treatment and is of particular interest in this series. In 80 per cent of the patients an experimental arsenical, thioarsine, was used entirely or in part. When used alone it was found to be unsatisfactory both from the standpoint of reactions and the clinical and serologic results as compared to arsphenamine.²⁶ Thus the role

of bismuth seems to be relatively more important in our results. Four patients of the series were, for experimental reasons, treated with initial courses of thioarsine before any bismuth was given.

The statistical results given in table 2 for the Cooperative Clinical Group were taken or calculated from the most recent evaluation of their material by Stokes and Usilton²⁷ and include only the results from patients receiving continuous treatment who were under observation for over two years. The most significant figures for comparison are those showing the relative amounts of bismuth given, the percentage of final reversals of the blood Wassermann reaction and the percentage of probable cures.

Some further explanation of the results is necessary. The data may not be comparable since many of the 1,423 Cooperative Clinical Group patients, although receiving continuous treatment, may not have received the full recommended course, whereas almost all of our patients received treatment according to plan. The 143 patients mentioned as receiving ideal continuous treatment and observed for from two to ten years would be more nearly comparable, but unfortunately complete statistics were not given for this group. A retardation in the reversal of the blood Wassermann reaction when bismuth and arsenical compounds are used simultaneously, a point recently emphasized by Beerman,²⁸ was noted in our series. The 91 per cent final reversal of the blood Wassermann reactions given for the Cooperative Clinical Group study was computed inversely from the 123 patients who still had positive blood Wassermann reactions at the end of the period of observation.

rapidly became permanently negative. These patients should not be considered in evaluating the effect of bismuth, thus leaving only four (7.4 per cent) relapses. These 4 include 1 instance of iritis which appeared during the first combined course and healed in eight weeks without necessitating any modification of the treatment.

TABLE 3.—Routine and Alternate Treatment Schedules for Syphilis of the Central Nervous System

Routine Schedule			Alternate Schedule; Same as for Latent Syphilis		
Week	Arsenical	Bismuth	Week	Arsenical	Bismuth
5	Daily intravenous injection of sodium iodide, 25-100 cc. (10% solution) and daily intramuscular injection of soluble bismuth (bismuth sodium tartrate, 1 cc. of 1.5% solution)		10	Bis. × 10	
4	Rest 4 weeks		4	4 weeks' rest

4	4 weeks' rest		4	4 weeks' rest	
6	Ars. × 6	Bis. × 6	6	Ars. × 6	Bis. × 6
18	34		18	44	

If cerebrospinal fluid is still positive, continue with courses of ten weekly injections of bismuth with two month rest periods indefinitely, plus tryparsamide or fever therapy if spinal fluid shows persistent prepatent changes.

If spinal fluid has become negative, taper off treatment with three courses of bismuth following increasing rest periods.

There were three serologic relapses. Two of these occurred after the six months rest period. They became and have stayed negative, one with further bismuth and autohemetic injections, the other, with two courses of combined therapy, one course of bismarsen and three courses of a bismuth compound. The third patient relapsed during the three months rest period. The entire routine treatment was repeated, producing an early reversal. However, during his six months rest period, after the second course of treatment, the blood again showed a 1 plus Wassermann reaction on one occasion. This became negative with further bismuth courses only and has remained negative for five years.

All of our patients with the possible exception of 10 in whom the spinal fluid was not examined (all patients who relapsed had negative spinal fluids) fulfil the requirements for a "satisfactory result" as defined by Moore—"All patients with reinfection; all those satisfactorily completing a year of probation (no lesions of syphilis, repeated negative blood Wassermann reactions, negative cerebrospinal fluid, normal physical examination); a few patients who had entered on but not yet completed the probationary year, with all findings negative."²⁹

Only 79.7 per cent "satisfactory results" were given by Moore²⁹ using these criteria in evaluating the Cooperative Clinical Group study. Stokes and Usilton²⁷ did not specifically mention any comparable figures, so the 91 per cent final reversal of the blood Wassermann reaction was also considered under percentage of probable cures.

The three complications due to bismuth that occurred were two instances of stomatitis and one gluteal abscess. No patients showed any significant urinary changes. A total of about 5,000 injections of bismuth compounds were given to the 55 patients. Two patients became

jaundiced during treatment. In both a diagnosis of acute catarrhal jaundice was made, and arsenicals and bismuth compounds were later given without further difficulty.

RESULTS OF TREATMENT OF ASYMPTOMATIC NEURO-SYPHILIS AND TABES DORSALIS

Probably because of the advent of more spectacular and rapidly effective methods of treatment for syphilis of the central nervous system such as fever, intraspinal or tryparsamide therapy little work has been done on the effect of bismuth in these conditions. There are a few early references to the beneficial effect of bismuth alone or in combination with fever therapy in both active tabes dorsalis and dementia paralytica.³⁰ Recently³¹ bismuth has been found the most effective drug for reversing the blood Wassermann reaction in syphilis of the central nervous system. As mentioned before, some physicians maintain that combined therapy gives fewer neurorecurrences and instances of late syphilis of the central nervous system. Bismuth has been demonstrated in the cerebrospinal fluid, and its passage into the nervous system seems to be facilitated by fever³² and also by alcohol.³³

The routine treatment for syphilis of the central nervous system as used in this study is outlined in table 3. When possible it was begun with five weeks' daily intravenous administration of iodides (25 to 100 cc. of a 10 per cent solution of sodium iodide and daily administration of soluble bismuth given intramuscularly (1 cc. of 1.5 per cent solution of bismuth sodium tartrate). If this was not feasible, the patient was given weekly injections of insoluble bismuth and iodides by mouth. Patients with clinical dementia paralytica or dementia paralytica fluid changes were, of course, imme-

29. Moore, p. 188.

The "basic" routine therapy just mentioned does not differ greatly in amount from that considered by the Cooperative Clinical Groups as "minimal prescribed routine treatment,"³⁴ which consists of twenty arsenical and twenty to forty heavy metal injections. Further therapy, however, consists again of the prolonged administration of bismuth compounds, specifically: If the cerebrospinal fluid is still positive after the basic routine treatment, courses of ten weekly intramuscular injections of bismuth compounds with two month rest periods are continued until it becomes negative unless there is evidence of clinical progression or the spinal fluid shows persistent predementia paralytica changes, in which case fever therapy is given. Routine treatment as referred to in tables 4 and 5 should be interpreted as meaning the "basic" bismuth-arsenical courses plus all further bismuth, i. e. all treatment except fever, intraspinal or tryparsamide therapy.

§ Twenty arsenical and forty heavy metal injections.

Tables 4 and 5 compare our results in the treatment of asymptomatic neurosyphilis and tabes dorsalis with as nearly comparable data as possible taken from the Cooperative Clinical Group studies:³⁵ A detailed analysis of cases based on the type of spinal fluid changes found was not significant in any of our data because of the comparatively small series. However, both the percentage distribution of the type of change found and the conclusion that the more severe the spinal fluid changes the more resistant they were to treatment were the same in both series. The important points brought out by both table 4 and table 5 are that not only do our final results appear better, as gaged by reversal of the changes in the spinal fluid and the low percentage of clinical and serologic progression, but these results are attained in a high percentage of cases by the prolonged use of bismuth alone rather than by the use of the more dangerous intensive measures such as fever, intraspinal and tryparsamide therapy.

35. O'Leary, P. A., and others: Cooperative Clinical Studies in the Treatment of Syphilis: Tabes Dorsalis, *Ven. Dis. Inform.* 19: 367 (July) 1938; footnote 34.

Many of our patients received truly massive doses of bismuth compared to the amount usually given, and the question of renal damage as the most likely serious result of chronic bismuth intoxication must be considered. The averages in metallic bismuth equivalents given for early syphilis, asymptomatic neurosyphilis and tabes dorsalis were 10 Gm. in three years, 13 Gm. in six years and 15.2 Gm. in six years respectively. The largest amount received by any 1 patient was approximately 35 Gm. over a period of eleven years. Periodic routine examinations of the urine were performed on all patients receiving antisyphilitic therapy. Although some patients occasionally showed traces of albumin there has been no evidence of serious renal damage. Several years ago at the suggestion of Dr. Cole renal function tests were made on several patients under treatment who had received considerable bismuth and the patients' kidneys were found to be normal. At the present time there is no evidence that there are any toxic effects from these large doses of bismuth.

SUMMARY

The twenty years experience with bismuth in syphilis therapy has shown that, although in some instances it will "cure" syphilis, it cannot be relied on as the sole antisyphilitic drug to the exclusion of the arsphenamines. Extensive studies of the many bismuth compounds advocated for intramuscular use indicate that the effectiveness of any one preparation depends on the ionizable bismuth which it makes available in the body. At the present time the consensus of opinion seems to be that bismuth salicylate in oil is the most suitable from the standpoint of the therapeutic effect, low toxicity and prolonged action.

Of the many complications reported from bismuth therapy, oral lesions and local manifestations at the site of injection are by far the most common though seldom serious. The greater proportion of complications could be avoided by proper oral hygiene and careful injection technic.

The method for the treatment of early syphilis presented differs from the usual one chiefly in the use of combined bismuth-arsenical courses, the continuous use of bismuth for the first forty to fifty weeks and tapering off of treatment with bismuth. About twice the usual amount of bismuth is used. The results of treatment of 55 patients with early syphilis by this method compare favorably with those of the Cooperative Clinical Group study for the continuous treatment of early syphilis. The respective percentages for the two systems were: final reversal of blood Wassermann reaction, 100 per cent and 91 per cent; relapses, 7.4 per cent and 7.7 per cent, and satisfactory result, 100 per cent and 79.7 per cent.

The results of a system of treatment for asymptomatic neurosyphilis and tabes dorsalis which uses prolonged bismuth therapy in place of the intensive measures such as fever, intraspinal and tryparsamide therapy also compared with the Cooperative Clinical Group results, in both instances the percentages of spinal fluid reversals, of progressions and clinical improvement being slightly in favor of the bismuth therapy. However, the important point is that bismuth produced these results in a great majority of patients without the use of fever, intraspinal or tryparsamide therapy.

The large amounts of bismuth received by these patients in no case caused any serious reaction or intoxication.

ABSTRACT OF DISCUSSION

DR. DONALD M. PILLSBURY, Philadelphia: Sobisminol mass has been approved by the Council on Pharmacy and Chemistry in the treatment of syphilis. It has been shown to exert a potent spirocheticidal effect in experimental syphilis. The experimental results have been good with the exception of those of Kemp, who did not find an adequate spirocheticidal effect in rabbit syphilis. I have used sobisminol mass by mouth in 87 cases of congenital syphilis. I have no clinical indication that it is not a potent antisiphilic agent. In common with the general criticism of treatment by mouth, I think one cannot be certain that the treatment is administered as directed. It had been hoped that with a rapid method of bismuth determination in the urine which has been reported on by Hanzlik and his co-workers it would be possible to determine whether or not patients were actually receiving the bismuth, as directed. I have found that the determination of the bismuth on individual samples of urine is absolutely without value in this regard. Patients in the ward who I was certain were being given the drug gave occasional negative results in the urine or a very low bismuth concentration was noted. This finding is also noted in the report of Barnett. I am at present continuing the use of sobisminol mass by mouth only for patients kept in the wards of the hospital who I can be certain are being given the bismuth compound and on whose urine determination on twenty-four hour samples can be made. Very large doses of sobisminol mass are necessary for children; older children are given the dose which is ordinarily employed for adults, that is 1,200 mg. of the mass daily. One objection to this type of therapy has been the high incidence of gastrointestinal reactions, not severe, not always necessitating discontinuance of this type of treatment, but certainly discouraging. This has occurred in over 25 per cent of the cases. Another objection to this method of therapy is that the cost of the drug is high, about 5 cents a capsule, and with 3 to 6 capsules a day being given, this amounts to a drug cost of 1 to 2 dollars weekly.

DR. S. WILLIAM BECKER, Chicago: The series which we have presented is very small, but we feel that our results have been good and the treatment is devised so that it can be administered in an office without a great deal of equipment and without hospital facilities. As a matter of fact, this treatment was devised because we do not have facilities for intraspinal therapy. We have a small hospital service, so that we could not hospitalize patients for hyperpyrexial therapy. We do not feel that trypanamide should be used except when other methods are contraindicated. I have felt for a long time that a combination of arsenical and bismuth therapy in syphilis is efficacious and tends to prevent relapses. Tatum has recently, as Dr. Walsh has stated, verified our impressions in the laboratory. The combination of arsenical and bismuth therapy from the therapeutic standpoint is additive but from the toxic standpoint it is not additive, evidently because the two drugs affect different organs in the body. Our present inclination is to start the treatment of early syphilis immediately with mapharsen and a soluble bismuth compound. The patient seen with the primary lesion or with very early secondary syphilis is given mapharsen and a soluble bismuth compound every other day for three injections and then treatment is continued at five day intervals. It is surprising that we have been able to give large amounts of bismuth, insoluble bismuth, without encountering any serious difficulty. This was impossible in the case of mercury. The patient who was given insoluble mercury intragluteally for some reason or other would suddenly have a large amount of this material absorbed, and toxic symptoms would be produced. We have never observed this particular complication in connection with bismuth therapy.

Some of the Contents of Cheese.—Whilst butter contains little more than the fat of the milk, cheese contains the casein, a large proportion of the valuable mineral salts and an important part of the vitamins as well.—*Nature*, Dec. 21, 1940, p. 796.

THE NATURE AND PATHOLOGY OF
RADIATION SICKNESS

VIRGIL H. MOON, M.D.

KARL KORNBLUM, M.D.

AND

DAVID R. MORGAN, M.D.

PHILADELPHIA

It has been known for years that severe, sometimes fatal illness may develop in patients subjected to intensive irradiation. Weakness, nausea, vomiting, oliguria, bloody diarrhea, rapid feeble pulse, low blood pressure and profound prostration are prominent clinical features. Both the metabolism and the renal elimination of wastes are markedly reduced. It has been observed that exposure of the abdomen to roentgen rays caused signs of illness more often than exposure of other areas. Death results from circulatory failure resembling that produced by anaphylaxis, severe intoxications, burns or intestinal obstruction.

Space is lacking to discuss the various theories offered as explanations and the extensive experimentation done in search for further evidence. Those interested in these matters are referred to reviews.¹ Hall and Whipple² and Warren and Whipple³ noted that the manifestations after extensive irradiation were like those of heat burns but with this difference: The latter produce illness immediately, while radiation sickness develops after a latent period. They noted also that the signs of illness resulting from acute intestinal obstruction are exactly like those following deep abdominal radiation. They showed that the latter produced delayed necrosis of the glands and of the epithelium in the intestinal mucosa and ascribed the illness to the absorption of products of cellular disintegration. The mechanism of this effect was like that which Whipple had shown in experiments on closed intestinal loops.

We were impressed by the close resemblance between the manifestations of radiation sickness, high intestinal obstruction or strangulation and those of shock resulting from various causes. We have reported⁴ on the development of shock incidental to intestinal obstruction. It seemed of interest to compare both the physiologic disturbances and the postmortem findings of radiation sickness with those which characterize shock. Our initial experiments were arranged to duplicate closely the roentgen technic employed by Whipple. The physical factors employed were 130 kilovolts, 5 milliamperes, 2 mm. of aluminum filter, and 30 cm. skin-target distance. The output of the equipment was 72 roentgens per minute. Open field irradiation was given over the abdomen of healthy, normal dogs in amounts ranging from 1,400 to 2,800 roentgens. These amounts were given in one application divided between two abdominal areas.

No effects were observed for twenty-four to sixty hours, after which signs of illness developed. There were loss of appetite, vomiting, diarrhea and a decrease in the output of urine. Traces of blood were seen in

From the Departments of Pathology and Roentgenology, Jefferson Medical College and Hospital.

Read before the Section on Radiology at the Ninety-First Annual Session of the American Medical Association, New York, June 12, 1940.

the urine, feces and vomitus. This blood was derived from capillary hemorrhages in the mucosae and was not of sufficient amount to affect significantly the total blood volume. Concentration of the blood was manifested by a progressive increase in the hemoglobin content and in erythrocyte counts. These symptoms progressed

tion showed capillovenous congestion and numerous capillary hemorrhages. The serous surfaces and the gastrointestinal mucosa were deeply congested. There was bloody fluid in the intestinal lumens, and the lining had the appearance of purple velvet. The evidences of damage were most pronounced in the mucosa of the small bowel. Microscopic examination showed varying degrees of degeneration and necrosis of the epithelium and congestion of the capillaries and venules. The liver and kidneys showed parenchymatous degeneration and congestion. The spleen was contracted and bloodless. No significant changes were seen in other organs. These are the characteristic appearances of the viscera in shock from all causes excepting hemorrhage.⁶

A dose of 1,860 roentgens given as described caused death regularly in three to five days. One dog (295) given 1,116 roentgens showed moderate illness and hemoconcentration followed by recovery. A dog (296)

Fig. 1.—Lungs of a dog after death by radiation sickness. All parts of the lung and the serous surfaces show diffuse capillovenous congestion.

and death from circulatory failure occurred usually within twenty-four hours after the onset of illness.

It has been shown⁵ that hemoconcentration is the earliest and most significant clinical sign of shock arising from any cause whatsoever. Accordingly, counts of red cells and hemoglobin estimates were made before irradiation for comparison with subsequent data. There was no disturbance in the state of the blood until the onset of symptoms. At this point hemoconcentration appeared regularly and progressed commensurately with the severity of the symptoms. The hemoconcentration ranged from 15 to 50 per cent. The signs of illness and other data in a typical experiment,

TABLE 1.—Data Concerning Dog 293

Date	Signs of Illness	Temperature	Hemoglobin, Mg. per 100 Cc.	Leukocytes	Erythrocytes
5/1	Normal, before treatment	101.2	12	11,400	5,800,000

4:30 p. m.	Refuses food	101.0	13	10,900	6,070,000
5/6 8:30 a. m.	Urine scanty, blood tinged; vomitus contains blood	101.0	18	6,250	7,230,000
12:00 m.	Diarrhea blood tinged; pulse rapid, extremities cold, dog very ill	102.0	18+	4,000	7,950,000

The animal was given 2,772 roentgens over the abdomen May 2, 1939 and died at 12:30 p. m., May 6.

Fig. 2.—Section of lung in figure 1, showing marked capillovenous congestion and edema.

dog 293, the first animal treated, are shown in table 1. The results of abdominal irradiation were concordant in all animals. These are summarized in table 2.

Postmortem examination showed a diffuse congestion of the viscera. The lungs were mottled and cyanotic in appearance (fig. 1). Microscopic examina-

given 1,488 roentgens showed more serious illness and hemoconcentration. It lost 20 per cent of body weight and died of terminal pneumonia thirteen days later. Thus 1,860 roentgens, applied to the abdomen, appeared to be the approximate lethal dose for dogs.

In one group of 7 dogs, radiation was given over the liver, the lower part of the abdomen being protected by lead shields. In 1 of these animals (331) fatal illness accompanied by hemoconcentration developed. The post-mortem observations were the same as those described previously. In another (333) slight illness developed accompanied by 12 per cent hemoconcentration, but the dog recovered. The remaining dogs in this group showed no hemoconcentration or evidence of illness. In 2 dogs (336 and 337), the liver and adrenals were shielded and the irradiation confined to the lower abdomen. These animals manifested typical reactions accompanied by hemoconcentration and followed by death. No illness resulted in 2 dogs (297 and 298) given 1,860 roentgens and 3,720 roentgens respectively

5. Moon, V. H.: Occurrence and Clinical Significance of Hemoconcentration, Ann. Int. Med. 13: 451, 1939.
6. Moon, V. H.: Shock and Related Capillary Phenomena, New York, Oxford University Press, 1938.

over the chest. These experiments corroborate the observations of Whipple and of others that the intestinal mucosa is more sensitive than other tissues to the injurious effects of irradiation.

One group of dogs (302, 303, 304 and 305) were treated as described but were killed at intervals of twenty-four to eighty-eight hours after exposure. This was done in order to make examinations of the intestinal mucosae at earlier stages after the injury. Sections of bowel and of other tissue were placed in fixative within five minutes of the death of the dogs.

leukopenia develops in cases of severity, while in the early stages and in sublethal degrees of shock, leukocytosis is often seen. In most of the experiments with fatal outcome, the number of leukocytes declined before death. In several nonfatal experiments there was a sharp rise in the leukocyte counts.

COMMENT

Some of the theories offered in explanation for radiation sickness have been purely conjectural and unsupported either by logic or by evidence. Thus

TABLE 2.—Summary of the Results of Experiments on Radiation Sickness

Study of such sections confirmed the findings of Whipple and his associates, who made similar studies. The evidences of damage were most obvious in the mucosa of the small bowel (fig. 3). The epithelium lining the crypts and covering the villi showed all stages of disintegration and destruction. Some crypts contained nuclear and cellular debris; others were empty. Some of the villi retained their epithelial covering while that in the crypts showed necrosis and disintegration. Other villi were completely denuded of their epithelial covering (fig. 4).

In most instances there were no significant changes in the rectal temperature. The leukocyte reactions varied in a fashion similar to those described in clinical and in experimental shock.⁶ It has been shown that

the suppositions that such illness results from the inhalation of ozone or other gases generated by the electric apparatus or that the patient is allergic to roentgen rays deserve little attention; likewise, the supposed effects of static electricity in the body, the presence of a "roentgen toxin" in the blood, the effect of glycogen depletion and endocrine imbalance.

Other attempts to explain the phenomena were based on similarities to known conditions. Thus the resemblance of radiation sickness to acute poisoning, to the effects of burns, of physical trauma, of profound intoxication, of anaphylaxis or of intestinal obstruction were comparisons based on clinical observations. Radiation sickness has items of pathologic physiology in common with each of those conditions, and the clinical features

present no characteristic differences. An increase in the nonprotein nitrogen, hydrogen ion concentration, dextrose, phosphorus and potassium content of the blood and a decrease in the chloride content, oxygen content, metabolism and in the total blood volume are found in the conditions mentioned, also in radiation sickness and in shock from various causes.

Many years ago, Edsall and Pemberton⁷ interpreted radiation sickness as a toxic reaction to products of cellular disintegration. Later Hall, Warren and Whipple conducted extensive experiments on the subject and came to the conclusion noted earlier in this paper. Rolleston¹ reviewed the various proposed explanations and found that the weight of evidence favored acute toxemia from products of cellular injury or destruction. These products, as shown by Lewis, cause dilatation and increased permeability of capillaries. This effect, if extensive, results in decreased blood volume, increased concentration of the blood, reduced volume flow and reduced delivery of oxygen, producing tissue anoxia, and thereby the mechanism of shock is initiated.⁶

Forfota and Karády⁸ cited numerous observations on the resemblance between radiation sickness and shock. They commented on the demonstrations by Ebbecke,⁹ Lewis¹⁰ and others that cellular injury of any kind causes the release of H substances which affect capillaries in the same fashion as does histamine. They compared the effects of histamine and of experimental radiation in dogs and reported that examinations of the blood showed the same essential variations from normal.

Our results have confirmed those of the authors cited; furthermore, our interpretations are similar. Exposure of the abdominal viscera to massive doses of roentgen irradiation causes delayed necrosis of the intestinal

parallel the recognizable epithelial injury. The resulting symptoms are those regularly seen in shock from other causes. The condition is accompanied by progressive hemoconcentration, and the visceral changes seen post mortem are characteristically those of circulatory failure of the shock type.

Fig. 2.—Mucosa of a dog (302) killed sixty-six hours after roentgen irradiation. The cells of the glands have disintegrated and the epithelial covering.

These experiments have a significant bearing on the mechanism of shock. Some writers assign this to local hemorrhage and loss of fluid or to sympathoadrenal hyperactivity and disregard absorption of products from damaged tissues as a factor. Injury to the intestinal mucosa by irradiation is like injury by heat or other physical agents, but with these differences: it produces delayed necrosis and causes no pain or emotional reactions. Hence such injury eliminates hemorrhage, anesthesia, pain, emotional reactions and sympathoadrenal hyperactivity as factors. In such experiments it appears that the disturbances of circulation result solely from absorption, independently of other factors.

SUMMARY

Exposure of the abdomen to high voltage roentgen irradiation causes physiologic disturbances like those of shock arising from other causes. This is accompanied by progressive hemoconcentration. The visceral findings post mortem are those characteristic of shock regardless of its origin. Deep roentgen irradiation causes delayed necrosis of the intestinal mucosa. The resulting signs of illness are likewise delayed in onset.

Irradiation provides a new method for inducing shock by injury to living tissues. This method eliminates the confusing effects of other factors including pain, emotional reactions, sympathoadrenal hyperactivity, hemorrhage and anesthesia.

ABSTRACT OF DISCUSSION

DR. CHARLES L. MARTIN, Dallas, Texas: Radiation sickness is of great interest to me because I have participated in a number of studies made on irradiated animals during the past twenty years. In 1919 Dr. Willey Denis and I investigated the blood chemistry of rabbits killed with large doses of roentgen rays given over the abdomen at the Massachusetts General Hospital. The blood concentration described by the authors was noted and was ascribed to a dehydration resulting from a severe diarrhea and an anorexia. The animals refused food and water and showed a suppression of urination and a loss of weight. It is my impression that this syndrome is not the same as that seen in shock. Small animals may be killed with doses of roentgen rays which produce no demonstrable change in the intestine, and death must be due to chemical or

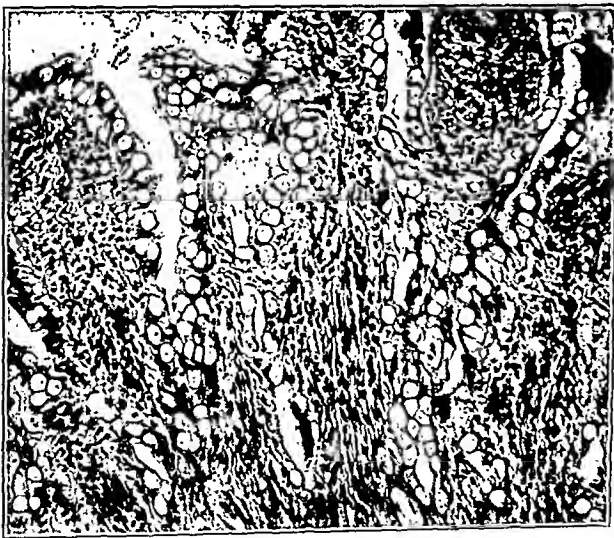

Fig. 3.—Mucosa of the small bowel of a dog (305) killed twenty-four hours after abdominal irradiation. Mucoid degeneration of the epithelial lining is present.

mucosa. Absorption of cytoplasmic material from this damaged tissue seems to produce the physiologic disturbances noted. The severity of the illness seems to

physiologic changes. Experiments that Dr. Fred Rogers and I reported a good many years ago proved that damage to the adrenal glands did not produce the fatal outcome. Although the mechanism of the process is still not understood, some work done recently at Baylor University with Dr. Walter Moursund convinces me that a vitamin B deficiency is one of the factors involved, and large doses of thiamine hydrochloride are of real value in the treatment of many patients suffering from radiation sickness. The Cincinnati group has been interested in this phase of the problem and I am told that they will soon bring forth some new helpful information. Certainly this field of investigation is still a fertile one.

DR. DAVID I. MACHT, Baltimore: In 1939 I published a paper on the blood pharmacology after exposure to roentgen rays. By using special pharmacologic methods which I have developed and have been using for some twenty years, in which living plant test objects are used for testing toxicity of the blood, I have examined the normal blood serum of various animals—dogs, cats, rabbits, guinea pigs, rats, mice and other animals—before and after exposure to various doses of roentgen rays. The results are interesting. One can show quantitatively and by experimental means (phytopharmacology is what I call this method) that there is a toxin, or at least a toxic reaction, developed in the blood, not immediately but twenty-four hours after exposure to the rays. That declines after a few days, depending on the dose. I thought it necessary to make these experiments on normal animals before going to clinical observations, and during the past two years I have collected some data of a clinical nature. I have examined by the same method twenty clinical cases, blood specimens from the Johns Hopkins X-Ray Clinic, some of malignant disease and others of benign conditions treated with roentgen rays, and all of them showed this toxic reaction. Furthermore, I have examined the blood of apparently normal persons, namely, roentgen ray specialists, physicians, nurses and workers in the roentgen ray laboratories. I took serums and tested them by phytopharmacologic methods, and all of them showed a toxic reaction. That is remarkable, because they were not complaining of anything, but it shows that roentgen rays do produce intricate biologic changes. I wish to add that such work as is being done by Wallace and Moon and their co-workers, and perhaps these attempts of mine on pharmacologic lines, are the kind necessary for combating or at least considering methods for rational therapeutic treatment of roentgen ray sickness, because these are the best objective criteria by which one can measure the blood or pathologic changes and tell whether the method of treatment is really effective or imaginary.

DR. ROSS GOLDEN, New York: Dogs, like human beings, may be made ill with very moderate doses of roentgen rays. In the winter of 1920-1921, in trying to investigate the question of acidosis as a cause of roentgen sickness, I had occasion to irradiate the upper abdomen of dogs. I found that by giving about what I thought was a human erythema dose at that time, probably somewhere around 400 or 500 roentgens, the dog could be made to vomit consistently about a half hour after irradiation was given. That could be kept up for a number of weeks. These dogs became emaciated and finally died, but it was three or four months after the inauguration of the experiments. These immediate effects on the dogs resembled clinical roentgen sickness, and it is rather difficult for me to correlate them with the authors' findings. I have seen patients get sick with 75 roentgens over the chest. I am wondering whether the authors could say something about the relationship of these moderate doses to obvious roentgen ray sickness. Perhaps they have some ideas about the immediate reaction, not a delayed reaction, which must be responsible for it.

DR. MOSES F. LUBELL, Waterville, Maine: I should like to ask the authors and Dr. Wallace what therapeutic agents they now recommend and whether they have had any experience with nicotinic acid.

DR. ROBERT P. NOBLE, Raleigh, N. C.: Why is it that some people do not get sick from small doses?

DR. VIRGIL H. MOON, Philadelphia: Let it be emphasized that we were interested in the acute manifestations. We made

no observations on the late or delayed results such as nutritional or metabolic deficiencies. We were interested in the syndrome as described that manifested itself by nausea, vomiting, diarrhea, low blood pressure, prostration and so on. We have not conducted any studies on the minor degrees either of that syndrome or of the late effects which lesser dosage of roentgen rays would produce at longer intervals of time. I was interested in Dr. Macht's observation concerning a toxemic factor. You will recall that the theory of traumatic toxemia of shock held the attention of medical men for a number of years after the World War. Later that idea was replaced to some extent by evidence which now has been discredited, and the original evidence has been confirmed. We now believe that shock resulting from trauma, from burns, from prolonged surgery or, as in this instance, from severe damage to the gastrointestinal tract by roentgen rays is due to some agent which exerts toxic effects on the endothelium of the circulatory system; and so, Dr. Macht, the idea of a toxic substance or toxic reaction is not out of our picture at all. I am deeply interested in the phytopharmacologic reaction that you mentioned, because certain other workers have used that test in histamine shock and in shock produced by other agents. They demonstrated by phytopharmacologic methods a toxic effect on young growing plants. In reply to Dr. Golden, our experiments were not designed to test the sublethal or late effects of irradiation. That is an important subject, but it does not have a direct bearing on this syndrome of circulatory collapse which develops incident to deep abdominal irradiation. Dr. Lubell, we have undertaken no therapeutic experiments either. We were concerned with the mechanism and have made no attempts at treatment. I am sure we will all agree with you, Dr. Noble; we should all like to know why some people do not get sick under the same circumstances which provoke illness in the average or normal person.

THE VIRUS OF POLIOMYELITIS IN STOOLS AND SEWAGE

JOHN R. PAUL, M.D.

AND

JAMES D. TRASK, M.D.

NEW HAVEN, CONN.

During the past two years it has become increasingly apparent that the virus of poliomyelitis may be readily isolated from stools of patients with poliomyelitis. Many reports¹ now testify to the ease with which this may be accomplished, not only from the stools of patients with the paralytic type² but also from those of patients with the common abortive type.³ In fact the stool method has quickly found its place in the study of this disease, and during this short period of time our knowledge of human carriers has been considerably enhanced. Already Lépine⁴ in Paris has followed one child con-

valescent from abortive poliomyelitis who harbored the virus in the intestinal tract as long as one hundred and twenty-five days, and Kramer and his co-workers,⁵ more recently in Detroit, have given a convincing report of "healthy intestinal carriers" in this disease. These observations point the way toward at least two lines of investigation which should throw light on the manner in which poliomyelitis spreads. One of these lines of approach lies in the clinical use of examination of the stool as a diagnostic test for detecting certain patients with poliomyelitis who have been overlooked and carriers of the virus of poliomyelitis; the other concerns the fate of the virus after it leaves the patient and "leaves the stool," as it were. For, obviously, if the virus is in human feces it must at least enter sewage, and the next epidemiologic query is How readily may it be demonstrated there?

A few investigations along both of these lines of approach will be reported in this paper. They include not only the use of the stool examination for the study of familial epidemiology in poliomyelitis but also some observations on the virus content of sewage.

TECHNIC OF STOOL EXAMINATIONS

Our procedures for the detection of the virus of poliomyelitis, together with the results of this type of examination on one hundred and eleven stools, are described in detail elsewhere.⁶ Briefly, the method has consisted in the dilution of a relatively small specimen (15 to 25 Gm.) of feces with sterile water. To this suspension 15 per cent ether is added for bactericidal purposes, and the suspension is allowed to stand overnight. About 30 cc. of this suspension is centrifuged at moderate speed for half an hour and from 12 to 20 cc. of the middle layer is then injected intraperitoneally into one or more monkeys. The most important aspect of the test, however, has been the subsequent care of the inoculated monkeys. Daily temperature and exercise records have been kept on these

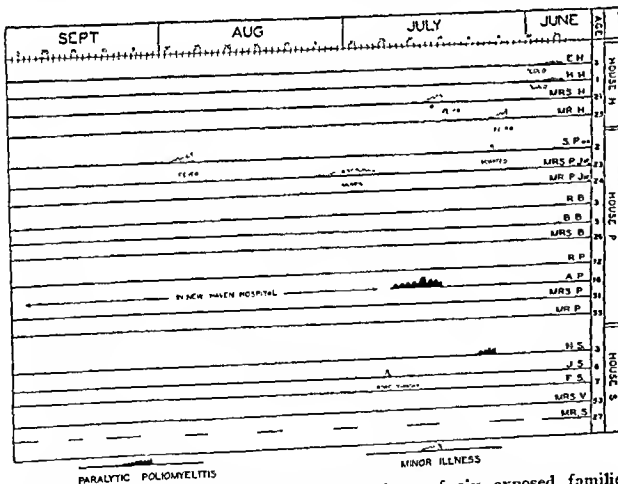

Fig. 1.—Schematic diagram of the members of six exposed families who lived in three houses. Each of the nineteen persons is designated by a horizontal line; the ages appear at the right. Legends on these lines mark the onset, duration and type of the various illnesses which occurred among this group during the summer of 1939.

animals for a period of four weeks, unless it seemed advisable to kill them earlier. If any monkey showed signs either definite or suggestive of poliomyelitis it

was killed at what seemed an appropriate time. Histic sections were examined from the medulla and from the cervical, thoracic and lumbar regions of the spinal cord of all killed monkeys, and if there were indications of poliomyelitis an immediate attempt was made to pass the virus to another monkey. If an animal died

during the four weeks of observation from some cause other than poliomyelitis, the test was considered unsatisfactory. In the series of stool tests reported in this paper, premature deaths of the inoculated animals were, unfortunately, unusually frequent; among 31 inoculated monkeys it occurred ten times. Criteria for a positive result will be taken up later in this report under the section which deals with the detection of the virus of poliomyelitis in sewage.^{6a}

CLINICAL OR FAMILIAL OBSERVATIONS

The present report describes the use of stool tests among a small group of persons during a rural epidemic in western Connecticut which occurred in the summer of 1939. Attention was first called to this situation in mid-July when A. P., a girl aged 18 years, was admitted to the New Haven Hospital with severe paralytic poliomyelitis. She came from a farm in rural Connecticut and was the first patient with the disease to be reported from that part of the state. Another patient with recent acute paralysis (N. S., aged 3 years) was soon discovered in the same community, and presently it became apparent that all the members of six related families who lived in three houses there had been exposed. This group was composed of nineteen persons, and besides the two with paralytic poliomyelitis there were several others who had acquired minor illnesses during late June and early July. The clinical events are best shown in the form of a diagram which gives the composition of the group and relates the various illnesses one to another in point of time (fig. 1).

Two of the patients with minor illnesses (Mr. and Mrs. H.) had symptoms compatible with those of abor-

S. Kramer, S. D.; Gilliam, A. G., and Molner, J. G.: Recovery of the Virus of Poliomyelitis from the Stools of Healthy Contacts in an Institutional Outbreak, Pub. Health Rep. 54: 1914 (Oct. 27) 1939.
6. Trask, J. D.; Paul, J. R., and Vignee, A. J.: Poliomyelitic Virus in Human Stools, J. Exper. Med. 71: 751 (June) 1940.

6a. Since this paper was written, Howe and Bodian (Untreated Human Stools as a Source of Poliomyelitis Virus, J. Infect. Dis. 66: 198 [May-June] 1940) have found it advantageous to use nasal instillations of unetherized fecal suspensions for detecting virus in stools. This we have corroborated in a small series tested during the summer of 1940. At present we use both the intranasal instillation of fresh stool suspension and the intraperitoneal inoculation of centrifuged, etherized material. Monkeys thus inoculated require at least five weeks of observation, instead of four.

tive poliomyelitis,⁷ namely fever, headache and malaise of two or three days' duration. In some of the other cases the symptoms were equivocal; one was a case of mumps (the last of an epidemic of this disease which had been present in one of the three households for some weeks).

To unravel this complex situation we set out to determine by stool tests how many cases of poliomyelitis could actually be detected in this group, how many carriers (either convalescent or healthy) could be detected and whether these facts could be integrated so far as the manner of spread of the disease in this group was concerned. In securing the necessary material we were fairly though not completely successful, for during late July and early August, 19 stool specimens were obtained from 18 of the persons mentioned; a few more specimens were secured later in the summer. The whole series of tests totaled thirty-one. An unfortunate shortage of monkeys during July and August made it necessary to pool many of these specimens, so that material from 2 or 3 persons often went into 1 monkey, and if this animal came down, tests were then made on the individual specimens.

The clinical circumstances under which each specimen was obtained appear in figure 2. Here it will be seen that the first stool giving a positive result was from the 3 year old child N. S. (the first patient with paralysis in the epidemic), who had reached the twenty-first day of her disease when the first specimen of her stool was obtained. Later, on the thirty-ninth day of her disease, her stool specimen was normal. The next stool positive for poliomyelitis was from J. S. (the brother of N. S.), whose illness was mild, and without this laboratory finding one would have been inclined to regard his sore throat and slight fever as trivial. On the second day of this illness his stool contained the virus; later, on the twenty-first day, it was normal. The third patient whose stool gave positive laboratory evidence was a 2 year old boy, S. P. (the nephew of the 18 year old girl A. P.). He gave no definite history of a preceding illness except an attack of vomiting three

unknown duration, such as those recently described by Kramer, Gilliam and Molner.⁵ The distinction between the two would indeed be slight. Arbitrarily, however, we have called him a convalescent carrier.

A glance at figure 2 indicates that besides the 2 paralytic patients (N. S. and A. P.) and the 2 adults with probable abortive poliomyelitis (Mr. and Mrs. H.) identified on the basis of symptoms, the minor illness of J. S. also turns out to be abortive poliomyelitis, and there is perhaps still another if we include S. P. These last 2 are diagnosed on the basis of laboratory findings. This gives a total of 5 or 6 cases, and we find that they occurred in three groups so far as their date of origin is concerned. Two (or 3) began on July 3 and 7, 2 on July 14 and 1 on July 24, giving three waves of illness separated by intervals of about ten days—which is the usual average incubation time given for poliomyelitis. The first 2 patients (N. S. and Mr. H.) may well have been exposed simultaneously to the same unknown source. This is plausible because the entire H. family together with the first patient (A. P.) was visiting in house S. during the last of June. Most of the subsequent cases possibly might have resulted from the same exposure, but it seems more reasonable to regard them as secondary and tertiary cases.

Up to this point this epidemic was a family affair, but subsequently the epidemic took a different turn. On the basis of the reports to the state department of health, there was a case about this time in Bristol and there were 3 cases in Waterbury, to be followed by 14 more cases from the western third of Connecticut. Their geographic relationship to the small focus of cases in figure 3. Most of the patients were admitted to the New Haven Hospital and most of their families were interviewed by us. In but 2 of the cases was there any history of association with the P. farm. This distributional relationship which the epidemic bore to the Naugatuck River (which drains off sewage and industrial waste from the city of Waterbury) implied that some factor existed in this epidemic which had to do with this watercourse. River epidemics like this one are not new or unique. Attention has been called to them in Sweden, Germany and Rumania by Kling,⁸

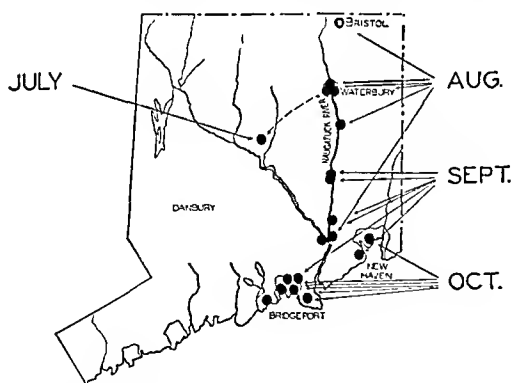

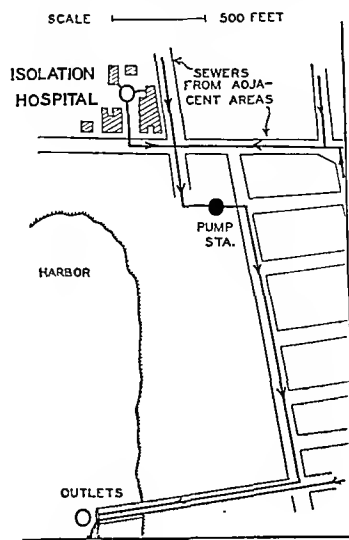

Fig. 3.—Map indicating the location of the building project downstream from house P.

weeks before. It is a question whether this indicates that the infant was a convalescent carrier early in the fourth week of his disease or a healthy carrier of

7. The terminology used for clinical poliomyelitis has been subject to frequent revision. Three terms are used here: paralytic poliomyelitis, abortive poliomyelitis and minor illness. The term minor illness is used in a special sense. It is applied here to those brief illnesses which occur so commonly among children during an epidemic of poliomyelitis, and it may be synonymous with the term suspected abortive poliomyelitis. Such minor illnesses may actually turn out to be abortive poliomyelitis, but at present they can be identified with certainty only if the virus of poliomyelitis is isolated from the patient.

○ SEWER TESTED—RESULT NEGATIVE
● SEWER TESTED—POLIOMYELITIC VIRUS PRESENT

Fig. 4.—Map of the southwestern corner of the state of Connecticut on which are marked all cases of poliomyelitis (19) which were reported from the western third of the state in 1939. In July there was only 1 case (A. P.), for the illnesses of N. S. and S. P. were not reported to the state department of health as definite cases of poliomyelitis. The broken line pointing to the city of Waterbury indicates a possible association between the July case (A. P.) and one of the Waterbury cases (C. G.). The distribution of the cases along the Naugatuck River and the progression of the epidemic down the river are noteworthy.

8. Kling, C.: Recherches sur l'épidémiologie de la poliomyélite, Acta Soc. Med. Suecicae 55: 23, 1929.

but they have received little notice of late in this country, although Caverly⁹ in 1894 described his classic epidemic as being largely restricted to the Otter River valley of Rutland County, Vt. No explanation is, however, offered as to the part that watercourses may actually play in spreading the disease. Tests of water from the Naugatuck River for virus in this epidemic were not made.^{9a} Nevertheless, from tests made elsewhere during the summer of 1939 it has become apparent that the virus of poliomyelitis may be present in sewage and that it may be transported for short distances by flowing sewage.

THE VIRUS OF POLIOMYELITIS IN SEWAGE

During the summer of 1939 there were several opportunities to study the natural presence of the virus of poliomyelitis in sewers during three large urban epidemics, viz. in Charleston, S. C., in Detroit and in Buffalo.¹⁰ Our experiences so far as the positive results are concerned will be briefly described here.

Primarily a few more words about the technical procedures and the interpretation of the tests are again necessary. The method for examining sewage for the virus of poliomyelitis is based essentially on that used in examination of the stool. It has been described in more detail in another paper.¹¹ Samples of sewage (usually amounting to 4 liters) were collected in the

Results of Tests on Sewage from Hospital K, Showing the Number of Inmates with Poliomyelitis at the Time of Each Test

Date	Poliomyelitis Virus in Hospital Sewer	No. of Hospitalized Patients with Poliomyelitis

morning. The specimens were allowed to settle for about two hours or longer and the supernatant fluid was then discarded. To the mid-layer (amounting to about 750 cc.) 10 to 15 per cent ether was added. The etherized specimens were transported (usually by airplane) to our laboratory in New Haven, and usually the day after their collection a dose of about 20 cc. was injected intraperitoneally into 1 or more rhesus monkeys. These animals were subsequently followed in the manner described under stool tests.

IDENTIFICATION OF THE VIRUS

One of the first questions that invariably arises when claims are made that the virus of poliomyelitis has been isolated from any unusual or extraneural source is How certain is it that it is the virus of poliomyelitis? Criteria on which the answer to this question is based will probably change from year to year, but those which we have used to define a positive result from sewage or stools are that the strain must fulfil at least three

9. Caverly, C. S.: Preliminary Report on an Epidemic of Paralytic Disease Occurring in Vermont, in the Summer of 1894, Yale M. J. 1:1 (Nov.) 1894.

9a. Since this article was written we have had occasion to follow another small local epidemic of poliomyelitis which occurred during the summer of 1940. Again it was more or less restricted to this same river valley. During the epidemic period a few tests of the river water, which was heavily contaminated with sewage, were made. Poliomyelitis virus was not detected.

10. Dr. Leon Banov, health officer of Charleston; Dr. H. F. Vaughan, commissioner of health, Detroit, and Dr. F. E. Fronczak, health commissioner, Buffalo, gave permission for these studies. These health officers and the members of their staffs, and also Mr. G. E. Symons of the Buffalo Sewer Authority, assisted in this work.

11. Paul, J. R.; Trask, J. D., and Gard, Sven: Poliomyelitic Virus in Urban Sewage, J. Exper. Med. 71:765 (June) 1940.

qualifications: 1. It must produce a "clinical picture" in the inoculated monkey which is compatible with that of experimental poliomyelitis, viz. after an appropriate incubation period a train of characteristic symptoms develops usually exemplified by fever, excitement, tremor, ataxia, weakness and paralysis, the latter being generally associated with a fall in temperature. 2. When the animal is killed, lesions typical of experimental poliomyelitis must be found in the region of the gray matter of the spinal cord, in lumbar as well as in cervical levels. These lesions should be "unequivocal," and besides their presenting evidence of neuronophagia there must be perivascular infiltrations with mononuclear cells. 3. Passage of the strain to a second monkey must be successfully accomplished, in the course of which criteria 1 and 2 must again be fulfilled. A fourth criterion is also valuable. It was used in almost all the sewage strains and consists in the injection of the strain (or the suspected material) into small laboratory animals such as rabbits, guinea pigs and mice. These animals should not acquire encephalomyelitis as a result of this inoculation. This last test should be helpful in differentiating the virus of poliomyelitis from that of lymphocytic choriomeningitis, equine encephalomyelitis and other viruses capable of producing an encephalitis or myelitis in these species, but it may be mentioned here that we have never succeeded in isolating from sewage any neurotropic virus other than that of poliomyelitis.

POSITIVE TESTS IN URBAN SEWAGE

During the summer of 1939, sixty-six tests were made on sewage collected in the course of the three urban epidemics just mentioned. Of these, thirteen were unsatisfactory, forty-five gave negative results, one gave a questionable result, and six gave positive results in that the three criteria were met, and one was positive so far as it went, for only the first two criteria were tried. The six giving positive results represented 4 different samples of sewage from two different sites. A strain from each of these 4 samples from the two sites fulfilled all four of the diagnostic criteria which we have considered useful in the identification of the virus of poliomyelitis.

In general the circumstances under which these few positive and many negative results were obtained indicated that it has been easier to isolate the virus of poliomyelitis from sewage collected in the vicinity of hospitals with poliomyelitic patients as inmates than from that gathered elsewhere. In the table five tests are recorded on sewage from one of the isolation hospitals in the city of Detroit. These tests were made on samples collected from a sewer pipe in the basement of the isolation building. The specimens here obtained on five occasions consisted of moderately cloudy or soapy water with a sediment of dark particles. Fecal material was not recognized as such grossly, but in spite of this "unpromising" looking material the virus was found repeatedly in this site. The relationship of the positive tests to the contemporaneous hospital populations appears in the table.

Besides the fact that the virus may be present in sewage, two other facts were determined: (a) that the total content of the virus of poliomyelitis in sewage may be large and (b) that the virus is stable enough to be transported by sewage for at least an eighth of a mile. Both of these facts were ascertained from tests¹² made

12. Brief details of these tests are recorded in a preliminary note (Paul, J. R.; Trask, J. D., and Culotta, C. S.: Poliomyelitic Virus in Sewage, Science 90:258 (Sept. 15) 1939).

from a pumping station in Charleston, S. C., during the recent epidemic there which lasted from April through July 1939. The circumstances are best shown by a diagram of the sewage system in the immediate vicinity of the pumping station where this positive specimen was secured in mid-July (fig. 4). (Negative specimens were obtained from this site in early August and in October.) Two monkeys were inoculated intraperitoneally with this material in doses of 120 and 125 cc. respectively. In both of these animals poliomyelitis developed, and later a third monkey was infected with a concentrate made from 100 cc. of the same specimen.¹³ Large as these three doses might have been, they were but "drops in the bucket" compared to the total volume of sewage pouring through this station, estimated at the rate of 470 gallons per minute. Theoretically, then, one could calculate that more than eighteen thousand doses of the virus of poliomyelitis infective for the monkey were passing through this site each minute of the hour in which the specimen was collected.

But of equal importance to the amount of virus in this large volume of sewage is the question of the source of the virus. If one assumes that this virus was of human origin, it then follows that it must have come either from patients in the isolation hospital or from patients or carriers in adjacent areas of the city (fig. 4) or from both. One conclusion that can be drawn from the positive finding is that whether or not the virus came from the hospital it seems to have survived in an urban sewerage system long enough to be transported for a distance of at least an eighth of a mile.

Other tests of sewage from this site which gave negative results are described in another publication. We did not succeed in isolating the virus from the many specimens collected after the major part of any of the epidemics was over.^{13a}

COMMENT AND SUMMARY

From these laboratory experiences it appears that newer methods of testing human feces and sewage have been of assistance in detecting the existence of the virus of poliomyelitis throughout an infected community during epidemic times. An example of this type of assistance is illustrated by tests on some of the patients in an epidemic in rural Connecticut. At the onset of this epidemic, the cases were confined within a relatively small area, and stool specimens were obtained from persons who were thought to have been intimately exposed. Subsequently the epidemic became more scattered, and in its spread attention has been attracted to a fairly large polluted watercourse along which some of the patients seem to have been grouped.

During that summer, river and harbor water and large volumes of sewage were tested in three urban epidemics which occurred elsewhere in the country. From these samples, tested during epidemic times, the virus of poliomyelitis was detected in two sewers both of which were in the vicinity of hospitals, and from these tests we learned that not only can the virus content of sewage be large but the virus may be transported, for short distances at least, by flowing sewage.

13. Gard, Sven: A Method for Detecting Poliomyelitic Virus in Sewage and Stools, *J. Exper. Med.* 71: 779 (June) 1940.

13a. During an epidemic of about 70 cases of poliomyelitis which occurred in Stockholm, Sweden, in the fall of 1939, Kling also was successful in isolating poliomyelitis virus from the local sewage (Levaditi, C.: Sur la présence du virus poliomyélique dans les eaux d'égout, *Bull. Acad. de méd.*, Paris 123: 335 [April 23-30] 1940). In our second series of sewage tests, carried on during the summer of 1940, a single positive result was obtained from a large sewer in New York City, which was not in the vicinity of an isolation hospital, although cases of poliomyelitis were present within the area this sewer drained.

It would seem unwise at present to make general statements about this finding so far as the epidemiology of poliomyelitis is concerned. We believe, as do others, that poliomyelitis is probably transmitted from one person to another by a number of different channels. Among these is the direct or indirect factor of close and intimate contact between infected persons, illustrated by the type of interfamilial contact in which juvenile members of a family usually share. Many of these infected persons may be convalescent carriers in the first few weeks of their recovery from either a diagnosed or a missed case; some of the exposed persons may become transient "healthy" carriers. But theoretically there may also be a variety of other channels in which contaminated food, milk and water, or conceivably insects, mammals or birds, play a part. That watercourses, and particularly watercourses polluted with sewage, may be related to one of these channels is suspected. The virus of poliomyelitis has never been isolated from "running water," but the tests herein reported show that it has been repeatedly isolated from "running" sewage. It is not evident from this last finding whether its presence in sewage is a direct or even an indirect link in the chain which leads this potentially infectious agent from one patient to another in this disease. Our observations merely call attention to in fact that the virus is there during epidemics.

789 Howard Avenue.

ABSTRACT OF DISCUSSION

DR. JAMES P. LEAKE, Washington, D. C.: The technic of Drs. Paul and Trask is the most important tool which has been developed for the epidemiologic study of poliomyelitis in years. They claim no originality, but they do deserve the credit. The high quality of their work on poliomyelitis is almost unique. It is only on the interpretation that there can be valid difference of opinion. I was glad to hear Dr. Trask say that in their study of clinical epidemiology it has seemed that what we ordinarily mean as human contact is that it is a method of transmission, by and large. One would infer from their figures that it is in the relatively young, and in those who have not in previous years acquired immunity to poliomyelitis, that we are most likely to have dangerous persons, dangerous in spreading the disease, and that is exactly the conclusion drawn from a study of the broad behavior of the disease in the United States over many years. Though their figures are small, they also tend to point to the nonparalytic and usually unrecognized case as being a more potent spreader of the disease than the recognized paralytic case. The general study of the disease apart from the authors' more exact study makes this obvious also. It is not clear to me, however, that healthy carriers may not be even more important than the nonparalytic or abortive or unrecognized cases of the disease. According to Trask, Paul and Vignette's published figures, about 15 per cent of their early cases were positive. They got this from the stools. From the fact that no positives were found among eight healthy contacts examined, one could say only that the incidence among such healthy contacts was less than 6 per cent. If such contacts for sampling were chosen among those who might have brought poliomyelitis into the family, they may have ceased to become carriers before the sample was taken. How does the virus get into the stools? That is a far different question from how the virus gets from one human body into another one. It seems to me it might well be that the virus might have been swallowed from nasopharyngeal secretions and discharged into the feces.

DR. T. M. RIVERS, New York: In spite of the good work that has been done, many questions regarding poliomyelitis remain unanswered. Indeed, there is no accurate yardstick whereby one can say that an individual case of illness is surely poliomyelitis and that an individual strain of virus unquestionably belongs in the poliomyelitic group. In addition, the matter of the portal of entry of virus in man and how the virus spreads

from man to man in nature are not clear; furthermore, there is an amazing lack of knowledge regarding the pathology of human poliomyelitis in relation to the idea of axonal transmission of the virus. All these questions are being vigorously attacked at the present time by a number of investigators. I should like to ask Drs. Paul and Trask two questions: Why is it that specimens of stools injected into the peritoneal cavity of monkeys bring them down with poliomyelitis in such a high percentage of cases, when fresh brain material full of active virus does not bring them down? How many instances of virus in the stool are they missing? We know that they have found it in a certain percentage of the cases and, if I am not mistaken, the percentage must be considerably higher than they have found.

DR. HAROLD L. AMOS, Greenwich, Conn.: The investigation of poliomyelitis may be divided into three periods: 1. The clinical and field studies of the previrus era, represented by the studies of Caverly and Wickman, pointed to the concept of dissemination of the virus through direct contact but more largely through persons with mild, abortive or subclinical forms of the disease. 2. The second period, initiated by the transmission of the disease to monkeys by Landsteiner and Popper, and the work of Flexner and Lewis, began a period of investigation which centered on the virus itself and the behavior of the experimental disease. The results of these studies were corroboration of the essential concept arrived at by the earlier studies, and then the implication of the nasal mucosa, or other barriers to the central nervous system, as determinants of clinical or subclinical infection on exposure to the virus. Later the application of the neutralization test for serologic immunity in epidemiologic studies revealed a process of immunization in the general population taking place to the same extent and with the same rapidity as with the more common widespread infectious agents, such as measles and diphtheria. Thus the concept of widespread dissemination of the virus, with limited occurrence of the paralytic disease, has held through the whole period of investigation. It has received corroboration and gained in stature at each additional step; furthermore, it has withstood the challenge of innumerable opposing theories. But this trend in thought and investigation has at no time been seriously, or for long, set aside. Many theories, on the surface more plausible, have been eagerly grasped and have had their day, only to fail when put to test or when further investigation has forced us back to the concept which now stands highest because of the support of valid, consistent observations. 3. In the first two periods the emphasis was placed on the virus itself, or exposure to the virus as the major factor in the determination of disease distribution, and the mode of spread of the virus was the central idea in epidemiologic studies. A third period, marked by the acceptance of widespread dissemination of the virus and a shift of emphasis from the mode of spread of the virus itself to the epidemiologic studies of the paralytic disease among those exposed, is represented by the trend of researches of the present and has further developed the idea that the occurrence of the paralytic disease among those exposed to the virus not only is limited but exhibits certain selectivities. These selectivities point not so much to factors of exposure as to factors in the exposed as a major determinant of the paralytic disease. The implications are that a disturbance of the intact mucous membrane during harborage of the virus is an etiologic factor in the disease.

DR. JAMES D. TRASK, New Haven, Conn.: Dr. Rivers asked us two questions. The first one is How many times did we miss finding the virus in stools? I think that this may have happened frequently. In the spring of 1939 Dr. McClure, of Albany, detected virus in the stools of five children during a small outbreak in Syracuse. Two days after him we collected stools from the same children and our tests were negative with all five. The second question of Dr. Rivers is Why does intraperitoneal inoculation of stool succeed when passage of monkey cord generally must be done intracerebrally? We think that the reason is that the spinal cord of inoculated monkeys frequently contains antibodies for the virus together with the virus. Thus as in the case with mixtures of antibodies and virus in other diseases (vaccinia, for example) passage may succeed with the intracerebral route when the subcutaneous or intraperitoneal routes may fail.

Clinical Notes, Suggestions and
New Instruments

SIGNIFICANCE OF HEMORRHAGIC TAP
IN APOPLEXY

A. H. TERRY JR., M.D.; SIGMUND FALK, M.D., AND
L. H. BRONSTEIN, M.D., NEW YORK

At one of the clinical conferences at the Beekman Street Hospital an intern unwittingly provided the stimulus for this paper, stating that he had never seen a patient recover who had a cerebral hemorrhage associated with a hemorrhagic or bloody spinal fluid. This started the ball rolling. Every one had a foggy prognostic idea but no one was sufficiently wise to settle the question. A search of the literature for the last ten years, as well as a review of the standard textbooks of pathology and neurology, failed to provide the answer. If the subject was touched on at all, a single statement that this was a poor sign was the sole conclusion—how poor a sign was never stated. The original articles in the literature safely attacked the problem from hindsight, analyzing autopsy material. Such studies disclosed that in cases coming to autopsy cerebral hemorrhages had a shorter existence when there was rupture into the ventricles. This showed which way the wind blew after the ship was wrecked but provided no barograph to protect the medical mari-

Results in 173 Cases of Hemorrhage or Thrombosis
of the Brain

Type Fluid	Hours					Hospital Days					Weeks		Survived	Died	Total

Bloody.....	8	11	5	3	4	3	2	1	1	3	..	2	41
Slightly bloody ..	1	..	2	1	1	1	1	2	1	1	2	10
Xanthochromic ..	1	1	1	1	3	4
Clear tap.....	1	..	2	6	2	..	5	1	1	2	2	..	20	22	42
No tap.....	5	16	6	3	5	5	1	3	1	2	2	..	20	49	69
Total.....														47	126

ner against the force of the storm when it struck. Our desire was primarily to know what prognosis to give patients admitted to the hospital, after cerebral accidents, with sanguineous spinal fluid. We undertook to eliminate vascular damage occurring at the base of the brain and confine ourselves to cases due to hemorrhage or thrombosis in the brain, commonly referred to as "apoplexy," "stroke" or "shock." We reviewed 173 such cases, and the results are here tabulated. The spinal fluid is referred to as bloody, slightly bloody, xanthochromic or clear. Sometimes there was no tap because the patient was too sick or too well or because the procedure did not meet with the approval of the attending physician. The length of survival is given in hours, days and weeks.

SUMMARY

- 1. Of 173 patients with cerebral hemorrhage or thrombosis, 47 (27 per cent) survived.
- 2. If there was hemorrhagic spinal fluid, 2 (less than 5 per cent) survived.
- 3. If there was slightly hemorrhagic spinal fluid, 2 (16 per cent) survived.
- 4. If there was clear tap, 20 out of 42 (about 48 per cent) survived.
- 5. When no tap was done, 20 out of 49 (40 per cent) survived.

COMMENT

No attempt is made to evaluate these statistics beyond satisfying the original question. All were hospital cases, perhaps worse than the regular run of the mill but nevertheless more illuminating than none at all, and they provide some kind of an answer to an incredulous hospital intern, and so to him the conclusion is that cases of apoplexy presenting hemorrhagic spinal fluid are 95 per cent fatal.

From the Beekman Street Hospital.

SCLERODERMA WITH PULMONARY FIBROSIS

JOHN R. MURPHY, M.D.; PHILIP KRAININ, M.D., AND
MARTIN J. GERSON, M.D., NEW YORK

The pathologic changes in diffuse scleroderma are not confined to skin and subcutaneous tissue alone but involve the connective tissue system throughout the entire body. Muscle, fascia, tendon, bone and at times even the endocrine glands and the internal organs participate in the disease process. Everywhere the same changes occur, namely edema followed by sclerosis of the collagenous bundles. This may occur in the connective tissue between the alveoli of the lung, the acini of the liver, the glomeruli of the kidney and the muscle fibers of the heart and within the pulp of the spleen.¹ The smaller arteries within the regions involved show corresponding sclerotic degeneration and thickening of the intima which may proceed to obliteration of the lumen and subsequent focal necrosis.²

The case to be presented is of interest because it has been possible to demonstrate visceral pathologic changes, namely pulmonary fibrosis or sclerosis as a clinical manifestation. A search of the literature of scleroderma has brought to light no other case in which the pulmonary manifestations of the disease were visualized by roentgenographic study.

REPORT OF CASE

History.—D. M., a Southern Negress aged 30, a housewife, entered the Morrisania City Hospital May 4, 1939, complaining of gradual loss of weight and a feeling of discomfort in the chest. During the past six months her weight had dropped from 115 to 102 pounds (52 to 46 Kg.). Since February she had noticed stiffness of her fingers and aching pains in her shoulders and arms. There was occasional cough, with expectoration of

Fig. 1.—Appearance of patient, showing sclerodactyly and masklike facies.

a small quantity of thin mucoid sputum, never blood streaked. In March she noted a tightening of the skin of her face and a thickening of the skin over her hands, forearms and legs.

From the Medical Service of Dr. David Greenberg, Morrisania City Hospital.

1. Cassirer, Richard, and Hirschfeld, Robert: *Die Sklerodermie*, in Kraus, Friedrich, and Brugsch, Theodor: *Spezielle Pathologie und Therapie innerer Krankheiten*, Berlin, Urban & Schwarzenberg, 1924, vol. 10, pt. 3, p. 557.

2. Masugi, M., and Yä, S.: *Die diffuse Sklerodermie und ihre Gefässveränderung*, Virchows Arch. f. path. Anat. 302: 39, 1938.

Shortly before admission she began to complain of some difficulty in breathing because of a sensation of "tightness in the chest."

The past history revealed no illnesses; she had not had pneumonia, pleurisy or frequent colds. For at least five years there had been a painless deformity of the finger tips and nails. The menses were regular, with onset at 12 years, of three days' duration. The menstrual flow had been scanty during the six

Fig. 2.—Section of epidermis and corium of patient with scleroderma (low power magnification).

months prior to admission. Her two children, 7 and 12 years of age, were living and well; there had been one miscarriage at two months. Both her parents had died late in life of pneumonia.

Examination.—The patient was poorly nourished, tall and thin, and not dyspneic or orthopneic. The facies was masklike and devoid of wrinkles and furrows (fig. 1). The skin of the face, arms and forearms, legs and feet was thickened and shiny; it was difficult to raise a fold of skin from these sites. Areas of mottled depigmentation were present over the nose, about the mouth and chin and on the anterior aspect of both legs. The thickening of the skin over the chest and abdomen was less obvious. The hands and feet were cold to the touch. There was shortening of the fingers and a clubbing of the terminal phalanges. The nails presented longitudinal striae. There was no limitation of motion of the extremities.

The pupils were equal and regular and reacted to light and in accommodation. The media were clear and the fundi presented a normal appearance. There were no abnormalities in the mucous membranes of the nose, throat or mouth. The skin of the neck was minimally involved in the sclerodermatous process and was freely movable; no lymph nodes were palpable. The trachea was located in the midline and the thyroid was not enlarged. The anteroposterior diameter of the chest was not increased, but the excursion of the chest appeared to be limited on inspiration. Percussion resonance over the lungs was impaired with diminished breath sounds throughout. No rales could be heard. The heart was not enlarged. There was regular sinus rhythm and the sounds were of good quality. The second pulmonic sound was accentuated and there was a soft apical systolic murmur. Blood pressure was 100 mg. systolic and 65 mg. diastolic. The abdomen was moderately distended but soft. The tip of the spleen was palpable. No abnormalities

were found on rectal or vaginal examination. The reflexes were physiologic and no abnormal neurologic changes were elicited.

A piece of skin was removed from the anterior aspect of the left leg and examined microscopically. The epidermis was of normal thickness with dense pigmentation present in the malpighian layer. The dermal papillae were flattened and indistinguishable from the remainder of the corium, which consisted of thick coarse bundles of collagenous fibers intertwining

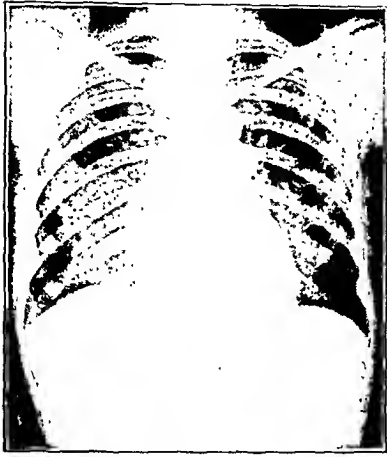

Fig. 3.—Appearance of chest, showing pulmonary fibrosis.

in all directions and containing few cellular elements. There was a marked increase in the thickness of the corium, the result of connective tissue sclerosis. Few small blood vessels were to be seen. There was a paucity of hair follicles and sweat glands. The subcutaneous fatty layer was much thinner than usual (fig. 2).

Röntgenographic examination of the chest showed no abnormality of the ribs or of the diaphragm, and the heart appeared within normal limits of size and shape. Within both pulmonary fields, exclusive of the apexes and the lateral aspect of the bases, there was a diffuse network-like shadow extending from the cardiac border to the periphery. This shadow was dense in the lower halves of the lung fields but thinned out and became strandlike in the subclavicular regions (fig. 3). Bronchography with iodized poppy-seed oil was performed, and this revealed a normal bronchial tree.

Except for small fragments of residual bone, the distal phalanges of the hands were absent and there was partial destruction of the distal half of the terminal phalanges of each fifth toe. The long bones were normal. There was a slight cloudiness of the left maxillary antrum.

An electrocardiogram revealed only left axis deviation.

Examination of the blood showed 11,000 leukocytes, of which 68 per cent were polymorphonuclears, 31 per cent lymphocytes and 1 per cent monocytes. There were 5.5 million erythrocytes with 78 per cent hemoglobin. The Kahn reaction of the blood was negative. Chemical examination revealed a serum calcium of 10 mg. per hundred cubic centimeters and again 10.1 mg., and a serum

Fig. 4.—Appearance of chest after right pneumothorax. Note absence of markings in the right side of the chest.

phosphorus of 4.5 mg. per hundred cubic centimeters. Serum phosphatase was 5.4 Bodansky units.

Serum cholesterol was 229 mg. per hundred cubic centimeters on one occasion and 200 mg. on another. Urea nitrogen was 7.2 mg. and dextrose 107 mg. per hundred cubic centimeters.

Venous pressure was equivalent to 7.5 cm. of water, and the circulation time was 7 seconds for ether and 15 seconds for saccharin.

The sputum was repeatedly negative for tubercle bacilli and a tuberculin test in the dilution of 1:10,000 gave negative results. The urine was normal and the basal metabolic rate was plus 11.

Course.—On the fifth day after admission the patient had a chill with a temperature of 105 F., together with swelling over the bridge of the nose. The lesion rapidly spread in butterfly fashion with a well defined border, so that within twenty-four hours the eyelids, forehead and cheeks were involved. The leukocyte count rose to 27,900 with 92 per cent polymorphonuclears. This was diagnosed as erysipelas. Sulfanilamide was administered and within forty-eight hours the temperature was normal and the facial swelling had almost completely disappeared.

During her stay in the hospital the patient gained weight, and the bone and joint pains disappeared. The sense of discomfort persisted but there was never any objective respiratory distress. She was discharged improved on August 2.

Because of the possibility that the pulmonary shadows viewed on the original roentgenograms might have been caused by sclerosis of the overlying skin and muscle, a diagnostic pneumothorax was performed on the right side and partial collapse was obtained. Check-up films revealed that the pathologic

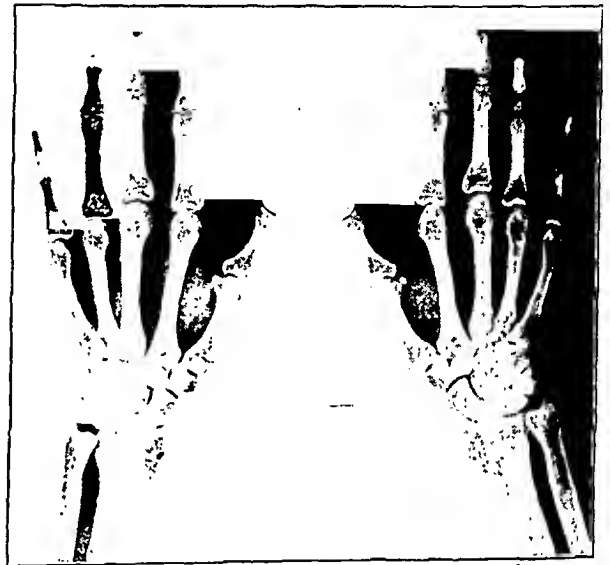

Fig. 5.—Appearance of hands, showing almost complete absence of distal phalanges.

changes previously observed were caused by a lesion within the lung and the appearance of fibrosis was not demonstrable in the soft tissues of the chest wall (fig. 4).

COMMENT

One may read many protocols of autopsies in which scleroderma was seen without finding reference to pathologic changes in the lungs other than incidental pneumonia, pleuritis, silicosis, tuberculosis and the like, all clearly unrelated to the disease process itself. Rarely, however, has a characteristic diffuse pulmonary fibrosis been described. The observers who have noted this are Notthafft,³ Matsui⁴ and Kraus,⁵ with a total of six cases. There was a varying amount of pulmonary emphysema in each case associated with hypertrophy and dilatation of the right ventricle of the heart. Histologically, the appearance was that of a "chronic interstitial pneumonia" with extensive connective tissue proliferation and thickening of the alveolar septums, together with changes in the associated blood vessels. The arteries showed marked proliferation of the intima,

hypertrophy of the media and infiltration with round cells. Matsui called attention to the disturbance in the lesser circulation resulting from interference with the pulmonary vascular bed, producing right ventricular hypertrophy. Roentgenographic studies of the lungs were not made.

Our case showed no evidence of cor pulmonale. The cardiac shape, circulation time and venous pressure were normal and the electrocardiogram showed left axis deviation. We feel justified in attributing the pulmonary changes viewed on the x-ray films⁶ to the sclerodermatous process, since there was no history of respiratory infections or exposure to dusts and since both bronchiectasis and tuberculosis could be excluded. The roentgenographic appearance of pulmonary fibrosis occurring in generalized scleroderma has never before been reported. Puddu,⁷ however, described fine calcified areas scattered throughout both lungs, visualized on the x-ray films, in a case of Thibierge-Weissenbach syndrome (scleroderma with calcinosis).

Special Article

GLANDULAR PHYSIOLOGY AND THERAPY

THE ESTROGENIC SUBSTANCES

EDWARD A. DOISY, PH.D., D.Sc.

ST. LOUIS

This special article is published under the auspices of the Council on Pharmacy and Chemistry. It is one of a series which will be published in book form as the second edition of "Glondulor Physiology and Therapy." The opinions expressed in these articles are those of the authors and not the official views of the Council.—Ed.

Although several investigators¹ contributed to the early development of research on estrogens, rapid progress did not begin until after the publication of the vaginal smear reaction² for the detection of these substances. The work was given additional impetus by the discovery of the high concentration of estrogens in the urine of pregnant women and in the urine of pregnant mares.³ These discoveries, which provided excellent sources of the estrogens and the means of quantitative determination, were of paramount importance to the isolation of the estrogens and the determination of their structure, as well as to the introduction of an ample supply of estrogenic substances for therapeutic use. The subsequent availability of pure estrogens has permitted an investigation of their role in sex physiology, particularly with respect to the estrous and the menstrual cycle, and of their interrelationships with other internal secretions.

CHEMISTRY OF ESTROGENIC SUBSTANCES

At this point a brief review of the chemistry of both the natural and the synthetic estrogens may prove valuable to the reader. According to a system of nomenclature proposed by a group of British investigators,⁴ the parent saturated hydrocarbon is named estrane, and the unsaturated hydrocarbon from which the natural estrogens are derived, $\Delta^{1,3,5}$ -estratriene. The first natural estrogen isolated in a crystalline form was named theelin by Doisy;⁵ according to its relationship to estrane, it is 3-hydroxy-17-keto- $\Delta^{1,3,5}$ -estratriene. For convenience this name has been abbreviated to estrone. The Council on Pharmacy and Chemistry of the American Medical Association recognizes as nonproprietary names both estrone and theelin.⁶

Natural and Synthetic Estrogens.—Estrone, or theelin, $C_{18}H_{26}O_2$, the first pure estrogen to be isolated, was obtained in 1929 from human pregnancy urine.⁷ Later it was obtained in crystalline condition from the urines of pregnant mares, stallions and men, from human placenta, from adrenal glands (probably beef) and from palm kernels. Its presence in sow ovaries was clearly indicated by physical, chemical and physiologic reactions. A conjugated form, estrone sulfate, has been isolated from mare's urine.

Estriol, or theelol, $C_{18}H_{26}O_3$, is obtained from human pregnancy urine,⁸ human placenta and pussy willows (?). A conjugated form, estriol glucuronide, has been isolated from human pregnancy urine. The relationship of estriol to estrone was established on conversion of the former to the latter by dehydration.

Estradiol, or dihydrotheelin, $C_{18}H_{26}O_2$, can be obtained by reduction of estrone in two isomeric forms, due to the new asymmetric carbon atom 17. The alpha compound has been isolated from sow ovaries,⁹ the urine of pregnant mares, human pregnancy urine and human placenta. The beta form has also been obtained from mare's urine.

Several other natural estrogens have been isolated. In 1932 three additional compounds, equilin, hippulin and equilenin,¹⁰ were obtained from the urine of pregnant mares. Subsequently, Wintersteiner and his collaborators isolated α -estradiol, β -estradiol and α -dihydroequilenin from the same source.

Owing to the minute concentration of estrogen and the large quantity of lipid contaminants, the isolation of estrogens from solid tissues did not proceed so rapidly. In 1930 Browne obtained estriol from human placenta, but it was not until 1938 that theelin and not until 1940 that α -dihydrotheelin were obtained from that tissue. α -Dihydrothecelin was isolated from sow ovaries in 1935, and the existence of approximately an equal concentration (about 6 mg. per ton) of theelin in sow ovaries was demonstrated in 1938.

Owing to the effect of certain types of adrenal tumors on sexual development, the isolation of estrone from adrenal extracts is interesting. Is estrone formed normally in the adrenal? If so, is this purposeful production, or is the substance merely a by-product of the steroid syntheses which seem to occur so profusely in the adrenal?

The synthesis of equilenin from simple starting materials by Bachmann¹¹ is one of the great accomplishments of the chemist in the sex hormone field. Although partial syntheses have given progesterone and several androgens, the production of equilenin is the first total synthesis of a sex hormone.

In addition to the synthesis of the natural estrogen, equilenin, several compounds having estrogenic properties have been synthesized. The first compound which was prepared, 1-keto-1,2,3,4-tetrahydrophenanthrene,¹² had relatively feeble activity, but finally compounds of exceptional potency were obtained. 9,10-Dihydroxy-9,10-di-n-propyl-9,10-dihydro-1,2,5,6-dibenzanthracene and triphenylethylene have a fair degree of activity, but stilbestrol and hexestrol have potencies of the same magnitude as estrone. Similar to the natural estrogens, stilbestrol and hexestrol have phenolic properties.

Chemical and Physical Properties of the Natural Estrogens.—Since all of the natural estrogens are phenolic and all other known sex hormones are not phenolic, a separation can readily be effected through the solubility of the former in aqueous alkali. The relative insolubility of the estrogens in purified petroleum benzine U. S. P. (petroleum ether) has been important in their separation from other lipids.

In all of the estrogens ring A is aromatic and, consequently, the hydroxyl on carbon atom 3 is phenolic. The only other point of substitution in the hydrocarbon structure is at carbon atom 17, at which either a carbonyl or a secondary alcohol is present. If the latter is present, two stereoisomers are possible, depending on the relative position of the hydroxyl.

Two reagents have been used successfully to separate the ketonic from the nonketonic estrogens. Trimethylaminoacetylhydrazide chloride (Girard and Sandulesco^{13a}) and carboxymethoxylamine (Wintersteiner^{13b}) react with ketonic estrogens

to form water-soluble derivatives. In addition to the reactions with these reagents, the ketonic compounds react with hydroxylamine, semicarbazide, acetylene and the Grignard reagents.

The phenolic hydroxyl reacts with a variety of compounds to produce esters; perhaps the acetate and benzoate are the best known. The 3,17 dihydroxy estrogens can be converted into 3,17 diesters, the 3-monocester or the 17-monoester. Esters of these types with several different acids have been synthesized by Miescher and Scholz.¹⁴ The 3 benzoate and 3,17 dipropionate of α -estradiol are used therapeutically.

Like simple phenols, the estrogens give color reactions with Millon's reagent, diazotized aromatic amines and Folin's phenol reagent. In addition, Kober^{15a} has shown that under certain conditions estrogens react with a mixture of phenol and sulfuric acid to give a red color, the intensity of which could be used for quantitative determinations. Cohen and Marrian^{15b} proposed a method for the separation of estrone and estriol and determined the estrogen of each fraction by a modification of the Kober reaction. Additional modifications of the Kober reaction have been proposed by Bachman.^{15c} Owing to the rapidity of execution and the accuracy of the results, it seems likely that in many instances these colorimetric analyses may displace determinations by bioassay.

The structure of the estrogens has been established through the contributions of several investigators. Butenandt, Weidlich and Thompson^{16a} showed that rings A, B and C are fused together as in phenanthrene; Haworth and Sheldrick,^{16b} that the hydroxyl in ring A is in the three position, and Cohen, Cook and Hewett,^{16c} that the estrogens are perhydro derivatives of 1,2-cyclopentenophenanthrene having the angle methyl group on carbon atom 13 and the oxygen atom on carbon atom 17. Confirmation of the accepted views of structure has been effected by the splendid synthetic work of Bachmann and co-workers,^{11a} in which a simple compound, 1-naphthylamine-6-sulfonic acid, has been converted by a series of reactions into equilenin. Since the conversion of equilenin into estrone had already been described by Marker, the structures of both estrone and equilenin are fully established.

BIOLOGIC REACTIONS OF THE ESTROGENS

As Edgar Allen¹⁷ pointed out in the first edition of "Glandular Physiology and Therapy," the estrogens are primarily growth-promoting agents. Certain of the more important reactions will be considered in some detail. Similar to the natural estrogens, the synthetic estrogen, stilbestrol, produces almost all, if not all, of the effects of the natural estrogens.

The Vaginal Reaction.—Early work on the ovariectomized rat and mouse showed that injections of estrogen were followed by growth of the vaginal epithelium, the thickness increasing from two or three to about fifteen cells.¹⁸ The sloughing of squamous

cells gave large cells with small nuclei or cornified cells typical of a response to estrogenic stimulation. This reaction has been used since 1923 in many assays of the estrogens. Without doubt the present advanced knowledge of the distribution and chemistry of the estrogens is due in large part to Edgar Allen's recognition of this reaction.

The work on vaginal smears has been extended to other species, but perhaps the most interesting development is the correlation by Papanicolaou^{19a} of the change in the vaginal smear with other phenomena of the sex cycle of women. Subsequently, Papanicolaou and others^{19b, c} have used the change in the smear as a guide to estrogenic therapy.

Estrogenic therapy for gonorrheal vaginitis²⁰ of prepuberal girls is based on the growth and thickening of the vaginal epithelium. Accompanying this growth, there is deposition of glycogen, with formation of a more acidic secretion. Biopsy specimens have shown the enormous growth that can be produced by proper medication with estrogens.

In the study of vaginal growth in animals the effects of colchicine²¹ have yielded interesting results. Although this drug does not stimulate mitosis, it arrests dividing cells in the metaphase, thereby causing accumulation of many mitotic figures. This has permitted observation of the marked increase of mitosis due to the injection of estrogens.

Uterine and Tubal Reactions.—The injection of estrogens produces cell division in both the epithelium and the muscular layers of the uterus. With the use of colchicine it has been possible to demonstrate clearly the increased cell division occurring in both the tubes and the uterus after injection of estrogens. In addition to the growth there is definite development of the uterine glands, with an increase in the amount of secretion in the lumens of the uterus and tubes. Markee's²² experiments in which a piece of endometrium was transplanted to the anterior chamber of the eye furnished an opportunity to observe in the living animal the effects of injections of estrogens, ovariectomy and related procedures.

Early work indicated that the administration of liquor folliculi to ovariectomized rats produced changes in the uteri indistinguishable from those in the uteri of rats in normal estrus.²³ Since this has been confirmed, using pure crystalline estrogens, there can be no doubt that estrogens are responsible for the growth and hyperplasia observed during the estrous cycle of the rat and

mouse. Moreover, Allen and others have shown that estrogens produce growth and hyperplasia in ovariectomized monkeys and that after cessation of injections bleeding occurs. This seems to be identical with the anovulatory menstruation of the monkey (Corner).

The increase in weight of the uterus following administration of estrogen was used for assay prior to the introduction of the vaginal smear. Recently, several investigators²⁴ have returned to the stimulation of uterine growth as a method of assay. However, it should be emphasized that with this procedure the animal can be used for only one assay.

Astwood and collaborators²⁵ have contributed an interesting analysis of the changes that occur in the uterus in response to the injection of estrogen. Six hours after the injection the uterine weight has increased appreciably, but the addition is due to water. Twenty-four hours later the composition of the uterus has been restored to normal, although the weight is greater than at the six hour interval.

In addition to the effects on the circulatory system and on uterine and tubal growth, estrogens have a pronounced effect in increasing uterine motility.²⁶

The discrepancy between the observations of different investigators as to the effect of estrogens on pregnancy seems to have been satisfactorily explained by the experiments which showed that administration of estrogen shortly after coitus causes locking of the tubes, in rabbits and mice.²⁷ The fertilized ova remain in the tubes and do not continue their development.

Mammary Reaction.—Growth of both the nipple and the mammary gland is stimulated by estrogens.²⁸ Sand has used the development of the nipples of males as an indication of the survival of transplanted ovaries.

In several species the injection of estrogen stimulates growth of the ducts, but in the guinea pig both ducts and alveoli respond with increased development. In strains of female mice which usually acquire mammary cancer the malignant growth is prevented by early ovariectomy. Moreover, Lacassagne has shown that the males of strains in which the females are susceptible to mammary cancer also show cancer in that gland if subjected to a course of estrogen injections.²⁹

Reactions of the Anterior Lobe of the Pituitary.—Castration is followed by cytologic changes in the anterior lobe of the pituitary, and the cytologic changes can be reversed by administration of estrogens. In addition to the cytologic change following castration, the anterior lobe contains an increased quantity of gonadotropin.³⁰

In young rats the administration of a large quantity of estrogen is followed by luteinization of the ovaries. According to one view, this is due to release of a luteinizing product of the anterior lobe of the pituitary. If the injection is continued over a longer period, the ovaries diminish in size, although the uterus and vagina show the effect of estrogenic stimulation. However, experiments have shown that the ovaries have suffered no permanent damage, since female rats which had been given daily injections for a month produced normal litters. Since this point has considerable importance in the treatment of gonorrheal vaginitis in girls, Allen and Diddle have studied the effect of prolonged treatment in monkeys. No permanent damage could be detected.³¹

In addition to their effect in altering the gonadotropic output of the anterior lobe, injection of estrogen exerts a suppressing effect on the output of the lactogenic factor and indirectly on the secretion of milk.³²

Effect on Calcium.—Although the effect on the serum calcium of birds has been a controversial point, it seems that massive quantities of estrogens do produce a striking increase. In the mouse, Gardner and Pfeiffer³³ have shown marked disturbances in calcium metabolism, in which the pelvis show resorption and the long bones show an increase in density due to the replacement of marrow by bone spicules.

Effect on Fowls.—In some varieties of birds feathering is influenced by the sex hormones. In addition to the production of female feathering estrogens produce hypercalcification of bones and an increase in serum calcium and blood lipids. Although the increase in lipids due to the injection of estrogens is very marked, the values are not so high as those observed during the laying season.³⁴

BIODASSAY OF ESTROGENS

Although an additional standard for the estrogen benzoates was provided by the Permanent Commission on Biological Standardization at the last meeting of the League of Nations (1935), it was the opinion of the participants that "as rapidly and as far as possible, the production of preparations of the oestrus-producing hormones should be limited to pure preparations of the different forms of the hormone and its chemically defined derivatives or of mixtures thereof, so that the activity may be indicated in exact weights, and indications in biological units may be abandoned."³⁵

In my opinion it is not feasible to assay against a standard any estrogen other than the estrogen of which the standard is composed. Only two standards have been furnished: estrone and α -estradiol monobenzoate. The members of the Commission realized that only preparations of estrone could be assayed satisfactorily against the estrone standard and only esters against the α -estradiol monobenzoate. To illustrate the discrepancies of assay when another estrogen is assayed against the estrone standard, estriol has been compared with estrone, mice being used for the assay. If each substance is given in a single injection of oil, the estrone is two hundred and sixty-six times as potent as estriol. If each is given in aqueous solution in four equal portions at intervals of twelve hours, the estrone is four times as potent as estriol. Depending on the solvent and on the division of the dose, estrone may be four or two hundred and sixty-six times as potent as estriol.

A similar situation exists with respect to the relation existing between estrone and α -estradiol. When each is given in aqueous solution in three portions during a nine hour period, the α -estradiol is ten times as active as estrone if rats are used for the assay but only twice as potent if mice are used.

In view of the past experience that each investigator has seemed unwilling to follow the assay procedure that a previous investigator has used, it appears that it would be wise to agree that since bioassay has served its purpose in guiding chemists to the preparation of pure estrogens, it should now be discarded, the products for therapeutic use labeled in metric units and their evaluation effected by the response of patients.

Metabolism of Estrogens.—A number of investigations have shown that the natural estrogens on administration to rats and mice are much less active when given orally than when given parenterally. It seems likely that the low potency following oral administration is not due to failure of absorption but rather to the fact that through the portal circulation the absorbed substance is offered first to the liver. Estrogens are rapidly destroyed by liver brei. Moreover, it has been shown that the heart-lung-liver preparation rapidly destroys estrogen, whereas the same system without the liver has little or no destructive action. A recent report gives interesting data on the effects of various tissue slices and of brei on estradiol, estrone and estriol.³⁶

After parenteral administration, only a small proportion of estrogen can be recovered from tissues or excreta.³⁷ Even measures to hydrolyze possible conjugated and less active forms did not appreciably increase the recovery. Two reactions which might explain the loss merit consideration: (1) oxidation and (2) reduction. The phenolic portion of the molecule (ring A) is a point of weakness at which oxidation can take place. In the urine of nonpregnant women Marker found two inactive reduced forms, estranediol A and estranediol B. Since these compounds have not been found in pregnancy urine, Marker believes that the metabolism of estrogens in the pregnant and the nonpregnant woman follows different pathways.

Several reports indicate that progesterone influences the metabolism of estrogen. A larger proportion of the injected estrogen is recovered when the organism has been treated with progesterone. Under these conditions a larger proportion of estrone or estradiol is converted to estriol. In the hysterectomized rabbit this change does not occur, thereby indicating that the uterus plays a part in the metabolism.³⁸

ESTROGENIC THERAPY

The earlier attempts at estrogenic therapy with aqueous solutions did not yield results that were entirely satisfactory. This was due in part to the limitation of the solubility of estrogens in aqueous solution and to rapid absorption and excretion. This situation was met by using neutral triglycerides, in which the estrogens are much more soluble and from which absorption occurs more slowly. At the present time some physicians are experimenting with pellet therapy, in which a compressed tablet of estrogen is introduced directly under the skin. In spite of certain obvious objections, this form of administration does insure slow continuous absorption of the estrogen over a long period.³⁹

From experiments on animals it seems that vaginal suppositories should be more effective than any other form of administration if it is desired merely to produce growth of the vaginal epithelium. Possibly this form of therapy is ideal for gonorrheal vaginitis in that responses other than vaginal may be restricted.⁴⁰

Although oral therapy may be more popular with patients, it seems that physicians have generally used preparations for parenteral use. No doubt, this was due in part to the prevailing evidence that in animals the natural estrogens were twenty or more times as active parenterally as enterally and in part to the desire on the part of the physician to secure more satisfactory control of therapy. Perhaps the recent experimentation with synthetic estrogens, ethinyl estradiol and stilbestrol, which are more active orally in animals will lead to an increased use of oral preparations when it has been satisfactorily established that such therapy is without danger.

With every woman of 40 years a prospective patient and actually a high percentage sooner or later being treated with estrogens, an experiment of tremendous magnitude is in progress. The acute undesirable reactions from ethinyl estradiol and stilbestrol which have been reported by some physicians have served as a definite warning that caution should be exercised.⁴¹ Furthermore, there seems during the last five years to be a definite trend toward massive dosage with both natural and synthetic estrogens. Perhaps this will

eventually prove to be satisfactory, but in the meantime it does not seem wise to be too incautious. Within another five or ten years any subacute damage which may have occurred will begin to make its appearance.

The increased incidence of malignant change following administration of estrogens to cancer-susceptible strains of animals serves as a definite warning. While it is true that the dose per kilogram of body weight is much higher than the amounts commonly used therapeutically in the human patient and that the most pronounced carcinogenic reactions are obtained in susceptible animals, still it seems unwise to ignore the possibility of accelerating or starting the growth of cancer in susceptible persons. Certainly, the treatment of patients having cancer or of patients from families with a history of cancer should be undertaken with a full recognition of the possibility of untoward results.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT.

THE COUNCIL ACCEPTS FOR INCLUSION IN N. N. R. SOME PRODUCTS OF ENDO PRODUCTS, INC.

Until recently no product of Endo Products, Inc., has been accepted by the Council on Pharmacy and Chemistry because of conflicts with the rules of the Council. On Jan. 12, 1938, the firm stated that it wished to cooperate with the Council. The firm has demonstrated its willingness to remove certain causes of conflict and has sent the Council a number of revisions of its catalogues. After considerable correspondence and negotiations, the Council voted to remove application of rule 11 from Endo Products, Inc. This action became effective June 5, 1940.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

OFFICE OF THE SECRETARY.

POLLEN ALLERGEN SOLUTIONS-SQUIBB (See New and Nonofficial Remedies, 1940, p. 37).

The following additional product, marketed in 5 cc. vials and having a potency of 10,000 protein nitrogen units per cubic centimeter, has been accepted:

Ragweed and Cocklebur Combined Pollen Extract-Squibb: (giant ragweed, dwarf ragweed, and cocklebur pollen extracts in equal proportions).

RACÉPHEDRINE (See New and Nonofficial Remedies, 1940, p. 242).

The following product has been accepted:

Racephedrine Hydrochloride-Upjohn.—A brand of racephedrine hydrochloride-N. N. R.

Manufactured by The Upjohn Company, Kalamazoo, Michigan. No U. S. patent or trademark.

Racephedrine Hydrochloride 1% in Modified Ringer's Solution: Contains in each 100 cc. racephedrine hydrochloride-N. N. R., 1 Gm., chlorbutanol, 0.5 Gm., sodium chloride, 0.85 Gm., potassium chloride, 0.03 Gm., calcium chloride, 0.025 Gm. and magnesium chloride, 0.01 Gm. dissolved in distilled water.

Capsules Racephedrine Hydrochloride 3½ Grain.

SULFANILAMIDE (See New and Nonofficial Remedies, 1940, p. 489).

The following dosage form has been accepted:

Tablets Sulfanilamide, 1 grain—The Upjohn Company. Prepared by The Upjohn Company, Kalamazoo, Mich. No U. S. patent or trademark.

Council on Foods and Nutrition

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

FRANKLIN C. BING, Secretary.

DESSERTS IN THE DIETS OF ADULTS AND YOUNG CHILDREN

It is the custom to conclude most meals, except breakfast, with some sweet, appetizing food which is more than ordinarily attractive in appearance as well as flavor. Such foods are known in the United States as desserts. Although some products in this class are of comparatively recent origin, the practice of ending a meal with a small portion of a sweet, attractive food appears to be as old as recorded history.

PHYSIOLOGIC SIGNIFICANCE

From the physiologic point of view the custom of ending the meal with a dessert probably serves two purposes, that of completely satisfying the appetite and that of providing a final psychic stimulus to the secretion of gastric juice. Those desserts with a high content of sugar or fat or both have a high satiety value. The presence of the sensation of appetite (and of the appetite secretion) is evidence of the physiologic fitness of the

baked custard or baked apple alone. Thus the pastry may be said to "dilute" the essential dietary value of the fruit or custard. If a method adopted by the Council for the rating of foods as sources of the various dietary essentials is applied¹ it is found that only the fresh fruits or those desserts in which milk or dairy products are the predominating ingredients can be rated as nutritionally significant sources of any of the dietary essentials other than calories. This method takes into account the caloric value of the food as well as the total daily requirement and the quantity of any given dietary essential which is supplied by a portion which can be conveniently eaten in one day.

The adult whose regular occupation demands a large expenditure of physical energy, or the physically active adolescent, usually may indulge moderately in cakes, other forms of pastry or other desserts which are rich in calories. Indeed, these desserts are sometimes a convenient and palatable source of the relatively large amounts of food energy the active person requires. It is essential, however, that the amount of caloric-rich dessert which is eaten does not reduce the intake of other essential food substances. Also desserts containing large proportions of sugar probably should be avoided even by physically active persons if they appear to be unusually susceptible to dental caries.

Persons who lead less active lives, particularly sedentary persons of small stature, require fewer calories, and the amount of

gastrointestinal tract to handle the food eaten, although normal digestion will proceed in the complete absence of appetite juice, which is secreted as a result of the sight, smell or taste of appetizing foods. Thus the serving of an attractive, palatable dessert may be considered a useful, though not indispensable, factor in the proper conditioning of the digestive tract for the performance of its normal function.

THE NUTRITIONAL SIGNIFICANCE OF DESSERTS IN THE DIET OF THE ADULT

Desserts vary widely in nutritional value, according to the ingredients of which they are composed. A dessert should be selected not alone for its appetite appeal but for its food value as well. Due consideration should be given to the contribution of the dessert to the composition of the diet as a whole.

Those foods now commonly used as desserts include fruit, pastry of all kinds, such as pies, cakes and other baked goods, pudding of all types, and the universally popular ice creams and other frozen desserts. The differences which may be found in the composition of average portions of representative desserts selected from each of the foregoing categories are illustrated in table 1. In general the table shows that those desserts which are richest in calories are proportionally poorest in other dietary essentials. This is explained by the fact that the higher caloric desserts such as cake and various other types of pastry are composed largely of refined sugar, fat (butter or, perhaps more often, some other suitably prepared animal or vegetable fat) and highly milled wheat flour. These ingredients, except butter, are notably deficient in dietary essentials other than calories. The table also shows that the nutritional values, other than calories, of desserts such as custard or apple pie are less than those of

high caloric dessert eaten must be carefully restricted if the diet is to be adequate in proteins, minerals and vitamins and at the same time is to remain within the limits of the caloric requirement. When planning adequate diets for the sedentary

Data for all products except fruit gelatin dessert are derived from recipes given by Mary E. Sweeney and Dorothy C. Buck: How to Feed Young Children in the Home, Merrill Palmer School, Detroit. Data for fruit gelatin dessert are derived from the recipes given by Mary E. Sweeney and Dorothy C. Buck: How to Feed Children in Nursery Schools, Merrill Palmer School, Detroit.

adult and the young child it is usually much simpler to attain success if high caloric desserts are completely eliminated from the menu. When included, even in modest quantities, it is difficult to plan a diet that is adequate in dietary essentials other than calories except for persons who require more than 2,500 calories daily.

1. Accepted Foods and Their Nutritional Significance, American Medical Association, Chicago, 1939.

Reducing or other calory-restricted diets frequently are limited to 1,500 calories or less. The milk, vegetables and other so-called protective foods which are the chief source of essential vitamins and minerals in the customary American diet themselves provide in the neighborhood of 1,000 to 1,500 calories when used in the amounts recommended by most experts in nutrition. Thus, in reducing diets the use of high calory desserts must be avoided. If used, these products inevitably will crowd out other and more essential foods or will result in a calory intake in excess of the requirement. Thus there results either more or less serious malnutrition, or the diet fails to accomplish its purpose of weight reduction. Desserts suitable for use in reducing or other calory-restricted diets are those which are themselves comparatively low in calories and which in addition provide nutritionally significant amounts of one or more dietary essentials other than calories. The data provided in table 1 show that fruits served without sugar or cream are preeminent among the desserts which meet these requirements.

DESSERTS FOR YOUNG CHILDREN

To provide adequate amounts of essential food constituents the diets of normal, healthy children usually should contain the following "protective" foods in approximately the quantities listed:

Milk, three or four cups daily.

Vegetables, two servings daily; if possible two besides potatoes. Green or yellow vegetables at least three or four times a week and preferably daily.

Fruit, one or two servings every day, with emphasis on citrus fruit or tomato juice. At least one of the fruits or vegetables should be served raw, particularly if citrus fruits or tomatoes are not readily available.

Three or more pats of butter or of oleomargarine which has been fortified with vitamin A. (Unfortified oleomargarine is undesirable in the diets of children because of its lack of vitamin A.)

Whole-grain cereal or whole-wheat bread or its nutritional equivalent in "restored" products, at least one and preferably two or more servings daily.

One or two servings of a protein-rich food other than milk, especially as the child grows older.

These foods alone will supply, in the portions suited to the young child, from approximately 1,200 to 1,800 calories. The total calory requirements of normal, active preschool children are of approximately the same order of magnitude. Thus it is apparent that, if the necessary nutritional values are to be provided, the diets of young children should not be "diluted" with desserts or other foods which serve only as a source of calories. If a dessert is to be included in the young child's diet it should carry its full share of the various dietary essentials.

In the distribution of the essential foods in the simple menus appropriate for the preschool child the citrus fruit or tomato juice, which serves as the main source of vitamin C, is customarily given as the breakfast fruit or as a part of a regularly scheduled midmorning feeding. The second portion of fruit, if two portions are given, may serve as the dessert for either the noon or the evening meal. The fresh or cooked fruit is best served alone and undiluted. Occasionally, for variety, the slightly sweetened undiluted fruit juice may be stiffened with gelatin and served with a suitable topping, or the fruit may be combined with other appropriate ingredients in the preparation of a simple pudding.

Milk also lends itself to the preparation of a wide variety of desserts, in which it may be used alone or combined with other essential foods such as eggs, whole grain cereal, and fruit or fruit juices. Such use of milk not only provides a satisfying and appetizing finish to the meal but affords an opportunity to vary the form in which this essential food is fed. This is frequently an important factor in inducing children to take the amounts of milk which are considered desirable.

REQUIREMENTS FOR ACCEPTED DESSERT PRODUCTS FOR YOUNG CHILDREN

There now are being marketed a number of prepared dessert products intended for feeding to invalids or to young children. No federal standards for the composition of these products as a class have been established. The Council, in considering such commercial products, has found it necessary to arrive at some nutritional standards for acceptable products in this group.

Acceptable commercial dessert products intended for use in the feeding of children or invalids should not be nutritionally

inferior to home-made desserts which are considered suitable for this purpose. The average proportions by weight of milk, fruit or fruit juice and other ingredients used in the home or institutional preparation of several simple desserts, which are suitable for young children, are listed in table 2. This table shows that the majority of these products contain at least 75 per cent of milk or fruit or of a combination of milk and fruit (or undiluted fruit juice) and that none contain less than 50 per cent of these ingredients. These proportions are therefore considered representative of good practice in the preparation of children's desserts.

On the basis of these facts and of the considerations discussed in the foregoing paragraphs, the Council has reached the decision: To be acceptable to the Council, commercial dessert products represented for use in the feeding of young children must contain milk or fruit or a combination of these two ingredients in amounts which constitute at least 50 per cent of the total weight of the product. Prepared desserts which contain less than 50 per cent by weight of milk or fruit or a combination of milk and fruit are not considered eligible for acceptance or for description in the book *Accepted Foods and Their Nutritional Significance*.

ACCEPTED FOODS

THE FOLLOWING ADDITIONAL FOODS HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO ACCEPTED FOODS.

FRANKLIN C. BING, Secretary.

PREPARATIONS USED IN THE FEEDING OF INFANTS (See Accepted Foods, p. 156).

H. J. Heinz Company, Pittsburgh.

HEINZ BRAND APPLE, FIG AND DATE DESSERT, a canned cooked mixture of apples, figs, dates, sugar and lemon juice.

Analysis (submitted by manufacturer).—Moisture 74%, total solids 26%, ash 0.6%, fat (ether extract) 0.2%, protein ($N \times 6.25$) 0.6%, crude fiber 1.0%, carbohydrates other than crude fiber (by difference) 23.6%, sucrose (Munson and Walker method) 21.3%, calcium (Ca) 0.039%, phosphorus (P) 0.019%, iron (Fe) 0.0027%, copper (Cu) 0.00012%.

According to report of biologic assay (1939) this product contains 7 international units of vitamin A, 6 international units of vitamin B₁ and 17 Sherman-Bourquin units of riboflavin per hundred grams. Report of chemical titration (1939) shows that the product contains 50 international units of vitamin C per hundred grams.

Calories.—1 per gram; 28 per ounce.

HEINZ BRAND LAMB AND LIVER STEW WITH MILK AND CEREALS, a canned cooked mixture of milk, white potatoes, lamb, celery, lamb livers, cream, carrots, rice, onions, corn starch, chicken livers, and sodium chloride.

Analysis (submitted by manufacturer).—Moisture 84.7%, total solids 15.3%, ash 1.3%, fat (ether extract) 2.2%, protein ($N \times 6.25$) 2.9%, crude fiber 0.7%, total carbohydrates other than crude fiber (by difference) 8.2%, sucrose (Munson and Walker method) 1.7%, calcium (Ca) 0.065%, phosphorus (P) 0.063%, iron (Fe) 0.0055%, copper (Cu) 0.00018%.

According to report of biologic assay (1939) this product contains 3,100 international units of vitamin A, 9 international units of vitamin B₁ and 73 Sherman-Bourquin units of riboflavin per hundred grams. Report of chemical assay (1939) shows that the product contains 64 international units of vitamin C per hundred grams.

Calories.—0.64 per gram; 18 per ounce.

HEINZ BRAND PINEAPPLE RICE PUDDING, a canned cooked mixture of crushed pineapple, milk, sugar, rice, eggs, cornstarch and sodium chloride.

Analysis (submitted by manufacturer).—Moisture 70.3%, total solids 29.7%, ash 0.7%, fat (ether extract) 0.6%, protein ($N \times 6.25$) 0.3%, crude fiber 0.3%, carbohydrates other than crude fiber (by difference) 27.8%, sucrose (Munson and Walker method) 17.5%, calcium (Ca) 0.051%, phosphorus (P) 0.033%, iron (Fe) 0.0014%, copper (Cu) 0.00008%.

According to report of biologic assays (1939) this product contains 38 international units of vitamin A, 9 international units of vitamin B₁ and 28 Sherman-Bourquin units of riboflavin per hundred grams. Report of chemical titration (1939) shows that this product contains 16 international units of vitamin C per hundred grams.

Calories.—1.18 per gram; 34 per ounce.

HEINZ BRAND PRUNE PUDDING, a canned cooked mixture of milk, prune pulp, sugar, farina, eggs, cornstarch and sodium chloride.

Analysis (submitted by manufacturer).—Moisture 70%, total solids 30%, ash 1%, fat (ether extract) 1.2%, protein ($N \times 6.25$) 2.4%, crude fiber 1.2%, carbohydrates other than crude fiber (by difference) 24.2%, sucrose (Munson and Walker method) 17.3%, calcium (Ca) 0.069%, phosphorus (P) 0.054%, iron (Fe) 0.0011%, copper (Cu) 0.00016%.

According to report of biologic assay (1939) this product contains 300 international units of vitamin A, 10 international units of vitamin B₁ and 70 Sherman-Bourquin units of riboflavin per hundred grams. Report of chemical titration (1939) shows that the product contains 64 international units of vitamin C per hundred grams.

Calories.—1.17 per gram; 33 per ounce.

SATURDAY, FEBRUARY 8, 1941

HEALTH AND PHYSICAL EDUCATION UNDER FEDERAL SUPERVISION

During the closing days of the last Congress a measure was submitted, under the sponsorship of the American Association for Health, Physical Education and Recreation, proposing federal appropriations totaling eventually \$200,000,000 a year "to promote national preparedness and the national welfare" by assisting the several states and territories in making adequate provisions for "health education, physical education and recreation in schools and school camps." The framework of this bill followed the customary pattern of federal subsidy legislation. State plans were to be submitted by state educational authorities for approval by the federal official to be charged with the administration of the bill, the United States Commissioner of Education. Throughout the proposal references were made to the important problem of health education of persons between the ages of 5 years and 20 years in schools and in school camps. A state school plan was required to provide, among other things, for a continuous school health service, exclusive of medical and dental treatment, to determine at least annually the health status of each pupil, for special health instruction for handicapped children, for health supervision to insure safe and sanitary school conditions "and processes for healthful living," and for instruction in nutrition, dental hygiene, first aid, effects of narcotic drugs and alcohol, and physical and mental hygiene. Similarly, in plans for school camps instruction in matters relating to health was to play an important role. Scant suggestion was to be found in the bill that the services of those most competent to deal with health problems, whether in schools, in school camps or elsewhere, were to be utilized in making effective its stated objectives. This measure did not receive congressional consideration and consequently died when the Congress automatically expired. Now a similar bill, in a modified form, is before the new Congress, H. R. 1074, introduced by Representative Schwert of New York. In its structure it follows its prototype, but specific references

to problems of health education such as those mentioned have been omitted. There has been added, however, a most unusual provision to the general effect that the scope of the activities to be carried on under the bill may be extended in a particular state apparently without any limit whatever if the legislature of that state decrees. Thus any state legislature could add the medical features which have been eliminated from the federal measure. The proposal suggests a most ambitious program, which is offered for prompt action as a part of national preparedness. No doubt hearings can be held to determine the need for the measure and the scope of activities it is planned to embrace.

This legislation is symptomatic of a widespread movement in physical education. The College Physical Education Association¹ has adopted a report of a special committee in which the importance of physical education to the defense of democracy is emphasized. This report points out that physical education includes programs of health education and physical education. It presents a series of recommendations for national organization and legislation, for defining the responsibilities of the association, for outlining local programs, for activity programs, for military training and drill, for health instruction, for health service and for professional training. In brief, the College Physical Education Association holds that it should study every piece of proposed federal legislation in this field and support "desirable federal legislation aimed at the improvement of the health of the people and the development of physical education, health education and recreation in the several states." The services of its members are offered to the federal defense authorities and the War and Navy departments and to the National Defense Council, as well as to the United States Public Health Service and to the United States Civil Service Commission for use in the development of national, state or local programs in health education or recreation. Cooperation is tendered also to other physical, health education and recreational associations "and others." The proposal recommends "that, in the main, no radical or sharp departures in the content of local programs be advised," but that efforts be made "to intensify and improve the activity programs" now under way. Extensive recommendations are made for activity programs, health instruction and health service, endorsing both military training and physical education but holding that neither should be regarded as a substitute for the other.

Under health service, thorough physical examinations and immunization programs are recommended, and it is suggested that all physical education activities be conducted in accordance with the results of medical examinations. The report recommends "that the col-

1. Report of the Committee on the Contribution of College Physical Education to National Preparedness, New York, College Physical Education Association, Dec. 30, 1940.

lege assume some responsibility for making appropriate medical or surgical service available to all students in need thereof." It urges that all opportunities be seized for the improvement of professional training.

The American Legion has published a national program of preparedness and defense through physical education, health education and recreation in schools and communities.² This is a twenty-nine page letter to its national and state offices outlining the program, of which the salient feature is that the legion stands ready to cooperate with existing agencies in the improvement and extension of existing programs in health education, physical education and recreation.

Physicians look with sympathetic interest on the desire to improve the health education and physical status of the American people and on contributions to wholesome recreations. They approve such proposals as the coordination of physical activities with medical observations and the promotion of programs of preventive medicine and dentistry, as well as the wider dissemination of information about healthful living. Physicians approve especially plans which wisely utilize, extend and improve the good work that is now being done. They oppose the expenditure of large sums of money on experimental programs or activities which call on unqualified persons to perform functions which belong in the medical sphere. The national defense will not be served merely by the injudicious increase of expenditures. The American people, as *THE JOURNAL*³ has already pointed out, is not a nation of physical weaklings, even though it may not have achieved a maximum of good health and physical fitness.

THE OXFORD TUBERCULOSIS VACCINE

Among the basic medical researches interrupted by the present European war, none are of greater clinical interest than the Oxford University¹ studies of the vole acid-fast bacillus as a prophylactic vaccine against human or bovine tuberculosis. Although the experimental evidence thus far collected by Wells and Brooke is regarded by them as statistically inconclusive, their evidence is nevertheless sufficiently striking to warrant the hope that the vole vaccine may in time prove to be of clinical value.

Three years ago Wells,² of the Sir William Dunn School of Pathology, Oxford University, described a fatal tuberculosis-like disease of the wild voles of the British Isles, from which he isolated a hitherto undescribed acid-fast bacillus. The vole bacillus grows

readily on Dorset's egg medium and will reproduce fatal tuberculosis-like disease if injected subcutaneously into laboratory bred voles but is almost devoid of pathogenicity for rabbits or guinea pigs. Massive doses (e. g. 5 to 10 mg.) of the living bacillus injected subcutaneously into guinea pigs may occasionally produce progressive disease and death. A smaller inoculum (e. g. 1 mg.) usually produces only a local abscess with occasional ulceration, which invariably heals spontaneously.

In their initial test of the immunizing power of this bacillus, a group of 3 guinea pigs was inoculated in the left groin with caseous material from naturally infected wild voles. Each guinea pig developed a local caseous lesion, but there was no sign of a generalized infection. Nine months later, after complete healing of the local lesion, each guinea pig, together with normal control, was injected in the opposite groin with 10^{-6} mg. of a month old culture of bovine tubercle bacilli of low virulence. The animals were killed six months later. Necropsies of the control group revealed extensive generalized tuberculosis involving the lungs, liver, spleen and lymph glands. With one exception the vole-vaccinated guinea pigs showed no involvement of the internal organ, the only macroscopically demonstrable lesion being a small local caseous nodule in the right groin.

The test was then repeated on a larger scale, a freshly isolated highly virulent strain of human tubercle bacilli being employed as the test organism. One group of 5 guinea pigs was vaccinated with 1 mg. of the vole bacillus. A second group received one tenth of this dose. Three months later both groups, together with an equal number of unvaccinated controls, were inoculated with 10^{-2} mg. of highly virulent human tubercle bacilli. All nonvaccinated controls died within three months, necropsies showing extensive generalized tuberculosis. Both vaccinated groups were killed at this time. None of the animals receiving the larger dose of the vole vaccine had developed demonstrable internal lesions, necropsies showing only a small local abscess. Among the animals receiving a tenth dose of the vole vaccine, only 1 developed a partially generalized tuberculosis, all others showing only a regressive local lesion. A single 1 mg. dose of the vole vaccine apparently gave almost complete immunity, with a less effective prophylaxis from a tenth of this vaccine dose.

In order to form a basis of prediction for the probable clinical value of the vole vaccine, each of a group of 52 guinea pigs was given four weekly injections of 0.5 mg. doses of the vole bacillus. Each of a group of 30 control guinea pigs was given four 7.5 mg. doses of BCG. Previous studies had shown that this dose of BCG is the optimum immunizing dose for guinea pigs. Five months after the last injection, half of the sur-

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

ESTABLISHMENT OF A BOARD FOR THE INVESTIGATION OF INFLUENZA AND OTHER EPIDEMIC DISEASES IN THE ARMY

Following is a statement sent by Surgeon General James C. Magee to the Adjutant General on Dec. 27, 1940:

The present expansion of the Army has been accompanied by an increase in influenza and other acute respiratory diseases among troops. In certain localities these diseases have reached epidemic proportions, but fortunately they are still relatively mild and their mortality is low. However, if we may judge from the experience of previous mobilization, this comparatively favorable condition probably will not continue. As larger numbers of selectees are brought together, the rapid passage of infection from one individual to another will probably cause an increase in prevalence, virulence and fatal complications. In fact, the possibility cannot be ignored that the Army may again be confronted by another pandemic of influenza of the virulent type which caused such a large proportion of the total deaths among our troops during the last war.

During that period one of the important agencies utilized in the campaign against infectious diseases consisted of special boards composed of the most competent specialists available in the country, either military or civilian, whose function it was to study such conditions among troops and to advise the Surgeon General as to methods of prevention and treatment. An outstanding example was the "Pneumonia Board" appointed in 1918 (Special Order 118, W. D., May 20, 1918). This board, which met at irregular intervals in Washington at the call of the Surgeon General, not only rendered advisory service of inestimable value but organized and directed the studies of groups of expert epidemiologists, bacteriologists, chemists and pathologists, who were sent to certain camps and hospitals to investigate and combat this disease.

Since the World War our knowledge of the acute respiratory diseases has been increased enormously. We now know that certain of the interpandemic types of influenza are caused by filtrable viruses, and as these viruses can now be isolated it seems probable that eventually it may be possible to develop specific methods for their prevention. In view of the progress made recently in the study of these diseases, which are of such vital importance to the health and welfare of American troops, it is considered of urgent importance that the Army make immediate arrangements to utilize every scientific facility available in this country in a concerted effort to control these diseases and to reduce their mortality to a minimum.

With this objective in view, authority is requested for the Surgeon General to appoint and maintain a board for the investigation of the etiology, epidemiology, prevention and treatment of influenza and other acute epidemic diseases in the Army, this board to consist of such prominent physicians and other scientists as may be required from time to time, regardless of whether or not they are in the military establishment or other federal services or civilians not in the employ of the federal government. Because of the rapidity with which the respiratory diseases strike and the explosive nature of certain of the epidemics, it is essential that the organization of the board be made flexible and that its activities not be hampered by unnecessary administrative delays.

It is therefore recommended that this board be formed essentially as follows:

(a) *Organization and Personnel.*—That the board consist of (1) a central body of such scientists and technicians as may be

required, which will meet at the call of the Surgeon General; (2) an additional group of such expert scientists and technicians as may be required as consultants, who will meet with the central body when called on individually by the president of the board; and (3) investigative teams, the number to be determined by the disease situation, each consisting of three or more scientists and technicians, who may be sent for temporary duty at military stations when deemed advisable by the Surgeon General for the study and control of epidemics. It is important that the total personnel for the board not be limited at this time but that it be subject to change from time to time as the Surgeon General may deem necessary to meet any emergency disease situation which may arise in the Army.

(b) *Status of Civilian Personnel.*—That the civilian members of the board who are not federal employees be paid transportation expenses and \$20 a day while on temporary active duty at meetings or on investigative assignments with military organizations.

(c) *Procedure.*—That the central body of the board hold meetings from time to time, at times and places designated by the Surgeon General, in order to study the available current information concerning epidemic disease in the Army, and to formulate and recommend to the Surgeon General plans for its further study and control.

(d) *Control.*—That when the Surgeon General selects a team to investigate an epidemic at a military station the personnel of the team will be ordered to report to the proper local authority for temporary duty and will remain under that authority until the work is completed. The investigators will conduct their studies according to instructions from this office with as little interference as possible with the routine care of the sick. They will have the privilege of direct communication with the Surgeon General through technical channels on technical matters, and all other communications will be routed through regular military channels. A final report of the results of each investigation will be submitted to the Surgeon General through the main body of the board.

This establishment of this board will make available to the Army the scientific resources of the country to assist in the program for the control of influenza and the other epidemic diseases which will undoubtedly arise in our expanding army. Incidentally, its existence will undoubtedly be a matter of great satisfaction to the citizens of the country, who, remembering the tragic experience of the Army with influenza in 1918, are so vitally concerned over the possibility of a repetition of that experience. Therefore, from the viewpoint both of developing an effective agency for the study and control of this disease and the national morale, authority for the immediate formation of this board is urgently requested.

JAMES C. MAGEE,
Major General, U. S. Army,
the Surgeon General.

On Jan. 11, 1941, the plan was approved with the following memorandum:

War Department, A. G. O., January 11, 1941—To the Surgeon General.

The plan outlined in the basic letter for the establishment of a board for the investigation of influenza and other epidemic diseases in the Army is approved, except that civilian members of the board who are not federal employees will be paid not to exceed \$20 per diem for any person so employed and necessary traveling expenses.

By order of the Secretary of War:

A. P. SULLIVAN, Adjutant General.

CHEMOTHERAPY FOR INFECTIOUS
DISEASES AND OTHER
INFECTIONS

CIRCULAR LETTER NO. 81

The data on which this circular letter is based have been prepared by the Committee on Chemotherapeutic and Other Agents and the Subcommittee on Infectious Diseases, of the Division of Medical Sciences, National Research Council. The Committee on Chemotherapeutic and Other Agents, chairman, Perrin H. Long, consists of Perrin H. Long, professor of preventive medicine, Johns Hopkins University School of Medicine, Baltimore; Francis G. Blake, professor of medicine, Yale University School of Medicine, New Haven, Conn.; John S. Lockwood, instructor in surgery, University of Pennsylvania School of Medicine, Philadelphia; J. F. Mahoney, senior surgeon, United States Public Health Service, Venereal Division, Research Laboratory, Staten Island, N. Y., and E. K. Marshall Jr., professor of pharmacology and experimental therapeutics, Johns Hopkins University School of Medicine, Baltimore. The subcommittee on infectious diseases, chairman, Francis G. Blake, consists of Francis G. Blake, professor of medicine, Yale University School of Medicine, New Haven, Conn.; Rolla E. Dyer, senior surgeon, United States Public Health Service, National Institute of Health, Washington, D. C.; Henry Helmholtz, professor of pediatrics, University of Minnesota Graduate School, and the Mayo Clinic, Rochester, Minn.; Chester S. Keefer, professor of medicine, Boston University School of Medicine, Boston; Stuart Mudd, professor of bacteriology, University of Pennsylvania School of Medicine, Philadelphia, and Thomas M. Rivers, director of the Hospital of the Rockefeller Institute for Medical Research, New York.

In compliance with a request from the Surgeon General, the National Research Council appointed a committee to summarize the present status of chemotherapy with a view to its application in the treatment of military personnel. The following outline records briefly the opinions and recommendations of that committee concerning infections and infectious diseases. Because of the rapid development of chemotherapeutic agents, it is likely that some of these recommendations will have to be modified from time to time. Certain measures other than chemotherapeutic are described briefly when it seems appropriate. However, it is impracticable, except in a broad way, to delineate the therapy of persons suffering from various infections. This outline is published, therefore, as a general guide for medical officers and is to be used at their discretion, with due consideration of all other factors which may be presented by each individual case. It is not intended that it will be used to the exclusion or neglect of other indicated therapeutic or nursing procedures.

The Medical Department will continue to supply therapeutic serums for patients who are sensitive to chemotherapeutic agents and for those who in the opinion of the responsible medical officer may be advantageously treated with such serums.

Therapy for the following conditions is discussed: (1) hemolytic streptococcus infections, (2) scarlet fever, (3) meningococcal meningitis, (4) purulent meningitis, (5) pneumonia, (6) gas bacillus infections and (7) staphylococcal infections.

HEMOLYTIC STREPTOCOCCUS INFECTIONS

(a) *Mild or Moderately Severe Hemolytic Streptococcus Infections, Such as Erysipelas; Mild Cellulitis and Tonsillitis.*

Specific treatment:

Sulfanilamide: Recommended as the drug of choice. Initial dose (oral): 2 Gm. Subsequent doses: 1 Gm. every four hours day and night, until five days of normal temperature have elapsed. (The subsequent dosage may be modified after forty-eight hours of normal temperature at the discretion of the medical officer.) Then stop the use of the drug.¹

(b) *Otitis Media.*—This condition is generally caused by hemolytic streptococci but may be caused by pneumococci or other organisms and presents a special case. Treatment should be started as outlined in the foregoing section; bacteriologic cultures should be made and if the infecting organism turns out to be a pneumococcus or a staphylococcus sulfathiazole should be substituted, the dose being 1 Gm. every four hours, day and night, until the patient's temperature has been normal for five days. Therapy should be continued by giving small doses, of 0.5 Gm. four times daily, for at least ten days after a clinical cure has been effected.

(c) *Severe Hemolytic Streptococcus Infections, Such as Meningitis, Septicemia, Severe Cellulitis, Acute Osteomyelitis and Acute Mastoiditis.*

Specific treatment:

Sulfanilamide: Recommended as the drug of choice. Initial dose (oral): 6 Gm. Subsequent doses: 1 Gm. every four hours, day and night, until the temperature has been normal for seven days. For acute streptococcal mastoiditis or osteomyelitis, administration of sulfanilamide should be continued in small doses of 0.5 Gm. four times daily for at least ten days after a clinical cure has been effected.

SCARLET FEVER

(a) *Active Immunization with Toxin.*—This procedure is not recommended for the following reasons:

1. High percentage of immune subjects among adults.
2. Five or more injections of toxin are usually required to produce immunity.

Exception: Active immunization should be used for nurses with positive reactions to Dick tests and for orderlies assigned to care for patients with scarlet fever.

(b) *Simple Toxic Scarlet Fever (Exanthematous Stage).*

Specific treatment:

1. Antitoxin: Recommended in all cases in which the disease is moderately severe to extremely severe and the patient is not hypersensitive to horse serum.²

1. The routine use of sodium bicarbonate is unnecessary in treatment with sulfanilamide and its derivatives. This applies wherever such therapy is recommended in this circular letter.

2. Serum should never be given to patients who have a history of asthma of any type or to those who have a history of hay fever. Whenever serum is administered, have a syringe containing 1 cc. of epinephrine hydrochloride, 1 to 1,000 solution, at the bedside of the patient in order that this drug may be injected rapidly if an anaphylactic reaction develops. Two tests for serum sensitivity are available, and it is frequently desirable to use both. The first consists of the intracutaneous injection of 0.1 cc. of a solution of the serum diluted 1 to 10 in sterile physiologic solution of sodium chloride. The reaction is positive if at the end of twenty minutes the wheal at the site of the injection has enlarged to the size of a nickel and has an area of redness about it. The second test is the conjunctival test. This consists of instilling 1 drop of a 1 to 10 dilution of the serum in sterile physiologic solution of sodium chloride inside the lower eyelid of the patient. If redness and swelling of that eye appear within twenty minutes, the reaction is positive. A positive reaction can be countered easily by instilling 1 or 2 drops of a 1 to 1,000 solution of epinephrine hydrochloride inside the lower eyelid, a procedure which should be followed with all positive reactors in order to prevent the rare instances of corneal ulceration. These tests are interpreted as follows: 1. If the ophthalmic and cutaneous reactions (Continued on page 514)

The antitoxin should be given in one dose as soon as the diagnosis is made, intramuscularly if the disease is moderately severe and intravenously if it is severe to extremely severe, according to the following schedule: moderately severe, 18,000 units; severe, 27,000 to 36,000 units, and very severe, 45,000 units.

2. Sulfanilamide: No therapeutic effect on the toxic stage. It should be used for prophylaxis of septic complications in the dosage of 0.5 Gm. four times daily for the period of quarantine.

(c) *Toxic and Septic Scarlet Fever (Exanthematous Stage).*

Specific treatment:

1. Antitoxin (globulin concentrated): Recommended as stipulated in the foregoing section. Patients with early septic lesions (purulent rhinopharyngitis, sinusitis, otitis media, mastoiditis or marked lymphadenitis, and so on) in general are actually or potentially more toxic than patients with simple toxic (uncomplicated) scarlet fever. The doses used should be larger, according to the following schedule: if the disease is moderately severe, 27,000 units; if severe, 45,000 units, and if very severe, 63,000 units.

2. Sulfanilamide: Recommended in addition to antitoxin for its chemotherapeutic effect on septic lesions. Initial dose: 6 Gm. Subsequent doses: 1 Gm. every four hours, day and night, until the temperature has been normal for five days; then 0.5 Gm. four times daily for the period of quarantine.

(d) *Late Septic Complications (Postexanthematous Stage).*

Specific treatment:

1. Antitoxin: Of no value; not recommended.

2. Sulfanilamide: Recommended; dosage and duration of treatment as given in the foregoing section.

(e) *Precautions.*

1. Antitoxin: The usual precautions employed in giving horse serum should always be used.² Serum disease may be expected in approximately 25 per cent of cases.

2. Sulfanilamide: Symptoms and signs of acute hemolytic anemia, neutropenia, drug fever, dermatitis and hepatitis should be watched for carefully and sulfanilamide stopped at once if they appear. (See also the last section of this circular letter, on toxic effects of drugs.)

MENINGOCOCCIC MENINGITIS

Specific treatment:

1. Serum: It is generally recommended that anti-meningococcus serum should not be used in the treatment of meningococcic meningitis. However, in individual cases, serum may be used if in the opinion of the medical officer it is indicated.

2. Chemotherapy: Sulfanilamide: Recommended as the drug of choice. The intrathecal administration of this drug is not indicated. Initial dose (oral): 6 Gm. Subsequent doses: 1 Gm. every four hours, day and night, until the temperature has been normal for seven days. Lumbar puncture is indicated only for diagnosis and subsequently only to relieve manifestations of increased intracranial pressure.

are negative, then antitoxin may be given by any route. 2. A definite wheal-like reaction, with surrounding erythema, indicates cutaneous sensitivity. 3. A positive ophthalmic reaction, with or without a positive intradermal reaction, indicates a probable systemic reaction. Serum should never be given if both the ophthalmic and the cutaneous reactions are positive and should be used only with the greatest of care if either the ophthalmic or the cutaneous reaction is positive. This warning also applies to the serum treatment of meningococcic meningitis, pneumococcic pneumonia and gas bacillus infections.

PURULENT MENINGITIS

In case the cause of a purulent meningitis is not promptly established, chemotherapy should, nevertheless, be instituted at once with sulfapyridine as follows:

Initial dose (oral): 4 Gm. Subsequent doses: 1 Gm. every four hours, day and night, until the temperature has been normal for seven days.

Sodium sulfapyridine should be used intravenously if oral treatment is impossible. If it is used, the initial dose is 0.06 Gm. per kilogram of body weight, made up in a 5 per cent solution in sterile, freshly distilled water. This solution is given slowly (fifteen minutes) by the intravenous route, care being taken not to get the alkaline material outside the vein, because if this occurs it will cause a slough. Solutions of sodium sulfapyridine should never be added to transfusion blood, solutions of sodium chloride or dextrose or other fluids for intravenous use. Subsequent doses should be calculated on the basis of 0.03 Gm. per kilogram of body weight and should be given by the intravenous route at six hour intervals; oral therapy with sulfapyridine should be started as soon as it is practicable.

PNEUMONIA

The specific prophylaxis and treatment of pneumonia are based on etiologic classification and diagnosis, which should be carried out promptly in all cases whenever laboratory diagnostic facilities are available.

Pneumonia is classified in two main groups: (1) primary, which occurs independently of any major predisposing cause, and (2) secondary, which occurs as a complication of a major predisposing cause, e. g. influenza, measles or pertussis.

Primary pneumonia is principally caused by the pneumococcus. Other bacteria, e. g. Streptococcus haemolyticus (beta), staphylococcus or Friedländer's bacillus, may occasionally be the cause.

Secondary pneumonia complicating such diseases as influenza or measles is of variable etiology, often mixed, sometimes indeterminate. The higher types of pneumococci, beta hemolytic streptococci and Haemophilus influenzae are the bacteria most frequently concerned. Staphylococci, the gram-negative micrococci and Str. viridans may be found.

(a) *Primary Pneumonia.*

1. Pneumococcic pneumonia (usually lobar).

Chemotherapy: Recommended as the method of choice in all cases for the following reasons: (1) highly effective, except in the aged with chronic disease; (2) effective against all types of pneumococci; (3) may be given at once without waiting for type determination; (4) administration technically simple and relatively inexpensive, and (5) also applicable to treatment of most bacterial pneumonia other than pneumococci.

Sulfathiazole is recommended as the drug of choice in all cases for the following reasons: (1) greatly superior to sulfanilamide in scope and effectiveness of therapeutic action; (2) at least equivalent to sulfapyridine in scope and effectiveness of therapeutic action; (3) causes much less nausea, vomiting and mental disturbance than sulfapyridine; (4) other untoward reactions are (probably) less frequent and less severe than with sulfapyridine, and (5) the problem of excessive acetylation is not encountered to the same degree as it is with sulfapyridine.

Administration of sulfathiazole should be started at once in all cases as soon as the clinical diagnosis is made, etiologic diagnosis being carried out at the same

time. Initial dose (oral): 4 Gm. Subsequent doses: 1 Gm. every four hours, day and night, until the temperature has been normal for seventy-two hours. In cases in which the disease is very severe, an initial dose of sodium sulfathiazole (5 per cent solution in sterile distilled water), amounting to 0.06 Gm. per kilogram of body weight, may be given *intravenously*. To patients unable to take sulfathiazole by mouth, intravenous treatment with sodium sulfathiazole (5 per cent solution in sterile distilled water) should be given. (The solution of sodium sulfathiazole need not be sterilized.) The initial dose of sodium sulfathiazole should be 4 Gm. Subsequent doses of 2 Gm. each should be given every six hours. Oral administration should be instituted as soon as possible.

bacteremia. If these amounts prove insufficient, subsequent doses of 100,000 units each should be given every eight hours.

Precautions: Force fluids to 3,500 cc. a day. The usual precautions employed in all intravenous serum therapy should be observed. Serum should not be given to hypersensitive persons.²

2. Hemolytic streptococcal pneumonia, Friedländer's bacillus pneumonia and staphylococcal pneumonia.

Sulfathiazole: Recommended in all cases. Method of treatment same as for pneumococcal pneumonia. Initial dose (oral): 4 Gm. Subsequent doses (oral): Begin with 1 Gm. every four hours; if response is not satisfactory, increase to 1.5 to 2 Gm. every four hours until improvement is definite; then reduce to 1 Gm.

*Manifestations of Toxicity Due to Drugs Noted in Hospitalized Patients**

Reaction	Drug		
	Sulfanilamide	Sulfapyridine	Sulfathiazole
Nausea and vomiting....	Fairly common	Frequent	Uncommon
Dizziness.....	Common	Common	Uncommon
Psychosis †.....	In 0.6% of cases; occurs early	In 0.3% of cases, occurs early	Very rare
Neuritis †.....	Very rare	Not reported	Rare
Cyanosis.....	Very common; occurs early and late	Faint; common; occurs early and late	Uncommon
Acidosis †.....	In 1.9% of cases; occurs at any time	Not reported	Not reported
Fever †.....	In 10% of cases, generally occurs on 5th to 9th day; may occur on 1st to 30th day	In 4% of cases, generally occurs on 5th to 9th day; may occur on 1st to 30th day	In 10% of cases, generally on 5th to 9th day
Rash †.....	In 1.9% of cases; may take any form; generally occurs on 5th to 6th day; may occur on 1st to 30th day	In 2% of cases; may take any form; generally occurs on 5th to 9th day; may occur on 1st to 30th day	5% of cases; nodular type common; may take any form; occurs on 5th to 9th day
Hepatitis †.....	In 0.6% of cases; occurs early or late	Not noted but reported	Rare
Leukopenia with granulocytopenia †	In 0.3% of cases; occurs early or late	In 0.6% of cases; occurs early or late	In 1.6% of cases; occurs early or late
Agranulocytic angina †..	In 0.1% of cases; occurs on 14th to 40th day; more frequent on 17th to 25th day	In 0.3% of cases; occurs on 14th to 40th day; more frequent on 17th to 25th day	Not reported but may occur
Mild hemolytic anemia....	In 3.0% of cases; occurs early and late	Rare	Not reported
Acute hemolytic anemia †	In 1.8% of cases; occurs on 1st to 5th day	In 0.6% of cases; occurs on 1st to 5th day	Very rare
Hematuria †.....	Not reported	In 8% of cases; generally occurs early	In 2.5% of cases; generally occurs early
Anuria with azotemia †..	Not reported	In 0.3% of cases; generally occurs during first ten days	In 0.7% of cases; generally occurs during first ten days
Hyperleukocytosis †.....	Generally in presence of acute hemolytic anemia	Generally in presence of acute hemolytic anemia	Not reported
Injection of sclerae and conjunctivae †	Not reported	Not reported	In 4.0% of cases; may occur with rash and fever; occurs on 5th to 9th day
Purpura haemorrhagica †	Not seen but reported	Not seen but reported	Not reported
Ocular and auditory disturbances †	Rare	Rare	Rare
Jaundice †.....	With acute hemolytic anemia or hepatitis	With acute hemolytic anemia or hepatitis	Rare
Painful joints †.....	Reported	Not reported	Reported, with rash
Stomatitis †.....	Rare	Not reported	Not reported
Disturbances in gastrointestinal tract †	Bleeding rare; diarrhea uncommon	Rare	Not reported

* The patients were adults; 1,000 were treated with sulfanilamide, 291 with sulfapyridine, and 271 with sulfathiazole.

† A sign that it is best to stop the drug and force fluids.

‡ A sign that it is imperative to stop the drug and force fluids.

Serum therapy: Homologous type antipneumococcus serum, preferably rabbit serum, recommended in addition to sulfathiazole therapy for: (1) patients with early stages of the disease (seventy-two hours after onset) only when they have failed to show satisfactory response to forty-eight hours of chemotherapy (this happens rarely) and (2) patients with late stages of the disease (seventy-two hours after onset), clinically unusually severe, who presumptively have bacteremia or who have failed to respond to chemotherapy alone.

Method of treatment: If the patient is not hypersensitive to serum (see footnote 2), it is recommended that an initial dose of 200,000 units of antipneumococcus rabbit serum of homologous type be given intravenously to patients with early stages of the disease who have not responded to chemotherapy and an initial dose of 300,000 units to those with late stages of the disease, in a severe form, who presumptively have

every four hours and continue until the temperature has been normal for five days.

Sodium sulfathiazole: Same as in cases of pneumococcal pneumonia.

Precautions: Same as those taken in cases of pneumococcal pneumonia.

(b) *Secondary Pneumonia.*

Prophylaxis: The possible value of chemotherapy with sulfanilamide and its derivatives in the prevention of bacterial pneumonia complicating such diseases as influenza and measles is not known at present. Specific recommendations are therefore not justified.

Chemotherapy: Sulfathiazole is recommended in all cases in which pneumococci, hemolytic streptococci, staphylococci or Friedländer's bacilli are found and believed to be of etiologic significance. The method of treatment, the dosage and the precautions are the same as in cases of primary pneumonia.

Comment: Chemotherapy with sulfanilamide and its derivatives is of no demonstrated value for many patients with bronchopneumonia of indeterminate (virus?) etiology; it is also of no demonstrated value against pulmonary infections with *Str. viridans* or *Haemophilus influenzae*. Results in treating secondary pneumonia, which is often due to a mixed infection, will, therefore, be variable, often disappointing and difficult to evaluate, even when bacteria known to be susceptible to the action of the sulfanilamide compounds are present in the patient's sputum.

GAS BACILLUS INFECTIONS

It is recommended that all rational surgical procedures, such as débridement, be carried out as soon as possible and that all necessary supportive treatment be administered.

(a) Serum Therapy.

In the light of present knowledge concerning the value of polyvalent tetanus-gas bacillus antitoxin in the prophylaxis and treatment of gas gangrene, it is recommended that the prophylactic and therapeutic use of these serums be considered when in the opinion of the attending medical officer their use for a given patient is indicated.

Prophylactic dosage: Polyvalent tetanus-gas gangrene antitoxin 5,500 units.

Therapeutic dosage: 20,000 to 40,000 units or more given intravenously, supplemented, if need be, by intramuscular injections. These doses may be repeated in from twelve to twenty-four hours, depending on the symptoms and the response of the patient to the initial dose.

(b) Chemotherapy.

(1) **Prophylaxis:** Sulfanilamide recommended *at present* as the drug of choice. Initial dose (oral): 6 Gm. Subsequent doses: 1 Gm. every four hours, day and night, for seven days or until definitive treatment is available. This period of therapy almost always eliminates the possibility of gas bacillus infection.

(2) **Treatment:** Sulfanilamide recommended *at present* as the drug of choice. Initial dose (oral): 6 Gm. Subsequent doses: 1 Gm. every four hours, day and night, should be given until the temperature has been normal for forty-eight hours; then 0.5 Gm. every four hours, day and night, until convalescence is completely established.

Crystalline sulfanilamide may be used *locally*, 0.1 Gm. per square inch of treated surface.

STAPHYLOCOCCIC INFECTIONS

(a) Localized Boils and Carbuncles.

(1) **Small furuncles:** Apply hot wet dressings until definite fluctuation develops. Lesions which do not evacuate themselves spontaneously after becoming fluctuant should be promptly incised and drained. Chemotherapy is not recommended for these minor staphylococcic infections.

(2) **Large boils and carbuncles:** Administer sulfathiazole in an initial dose of 4 Gm. and 1 Gm. every four hours thereafter for seven days. Apply hot fomentations. Incise as necessary after fluctuation develops in order to encourage the evacuation of necrotic slough. Avoid incision of uninfected tissue or of diffuse cellulitis.

(b) **Diffuse Cellulitis, Lymphangitis and Acute Osteomyelitis.**

1. Immobilize the infected part in a splint and elevate it continuously.

2. Apply bulky gauze dressing, wet with saline solution, and keep dressing warm, if possible.

3. Give sulfathiazole: Initial dose: 4 Gm., followed by 1.5 Gm. every four hours thereafter. Continue use of the drug at this dose level as long as evidence of spreading infection continues; then reduce the dose to 1 Gm. every four hours and continue for at least seven days.

4. Employ surgical treatment for any areas of localized suppuration which may develop.

(c) *Staphylococcic Bacteremia.*

1. Give sulfathiazole: Initial dose: 4 Gm., followed by 1.5 Gm. every four hours until the patient's temperature has been normal for forty-eight hours. Then reduce the dose to 1 Gm. every four hours and continue at this level for fourteen days. The likelihood of relapse is great unless prolonged, continuous chemotherapy is employed.

2. Make every effort through careful clinical and roentgen examination to identify foci of distribution and localization. These should be treated by surgical drainage if they are accessible. Sulfathiazole may control invasive manifestations of infection but will not, by itself, bring about a cure of areas of localized infection, and reinvasion from such areas is likely if they are not drained.

(d) *Chronic Staphylococcic Suppuration (as in Chronic Osteomyelitis).*

1. Maintain drainage by packing with petrolatum gauze to the depths of the wound until sequestration of necrotic bone and tissue has occurred and the wound is covered with clean granulations.

2. Oral administration of sulfathiazole is not of much value. Local application of powdered sulfathiazole may be helpful but is still in the experimental stage and cannot be definitely recommended.

TOXIC EFFECTS FROM ADMINISTRATION OF DRUGS

In the table are listed some of the toxic effects which have been noted when treatment with sulfanilamide or one of its derivatives has been employed.

It is to be recommended that when possible laboratory control of bacterial chemotherapy be carried out, but inability to do examinations of the blood and urine should never be considered a contraindication to the use of the sulfanilamide compounds. If facilities are available, hemoglobin determinations should be done every other day during the first week of treatment and once a week thereafter. Total and differential white blood cell counts should be done every other day for the first seven days and (particularly important) if the patient continues treatment with sulfanilamide or its derivatives, every two days between the fourteenth and the fortieth day. Examinations of the urine should be done on alternate days for patients who are receiving sulfapyridine or sulfathiazole. The urine should be examined microscopically for blood. The output of urine of patients being treated with sulfathiazole or sulfapyridine for serious infections should be recorded daily. Patients receiving sulfanilamide compounds should be seen at least once a day and should be questioned as to the presence of headache or malaise. These are frequently important early symptoms of toxic reactions. Patients should be inspected at each visit for the presence of jaundiced scleras (acute hemolytic anemia or hepatitis), pale mucous membranes (acute hemolytic anemia) or rash. The temperature should be recorded. If fever occurs after the patient's temperature has been normal in the course of treatment with

sulfanilamide or one of its derivatives, the drug should be discontinued immediately or if recently discontinued should not be resumed unless it has been demonstrated that the fever is due to a recurrence of the infection. Whenever therapy with the sulfanilamide drugs is stopped because of a drug reaction, fluids should be forced so that 5,000 cc. a day is taken in order to wash out the drug.

Agranulocytosis is extremely rare before the fourteenth day of therapy. It is imperative that total and differential white cell counts be made for patients still under treatment after the fourteenth day, every two days from the fourteenth to the fortieth day. If the

percentage of polymorphonuclear leukocytes falls to 50 per cent or less in an adult patient, the drug should be stopped immediately. Granulocytopenia without acute agranulocytosis may occur.

Any patient who has had a toxic reaction to one of the sulfanilamide group of drugs may have a second, and more severe, reaction if one of these drugs is prescribed again. To such patients a small test dose of the drug (0.1 to 0.3 Gm.) should be given and the patient observed for twelve hours before intensive therapy is started, following which the patient must be carefully observed and the drug immediately stopped on the first appearance of any toxic manifestation.

SYMPOSIUM ON MILITARY MEDICINE

The California Medical Association and the San Diego County Medical Society sponsored a symposium on military medicine in San Diego February 1-2, under the chairmanship of Captain Chambers, commanding officer, U. S. Naval Hospital, who was supported by Capt. John D. Manchester, U. S. Navy, medical corps, retired; Rear Admiral Charles A. Blakeley, commandant of the eleventh naval district, and Major General William P. Upshur, commandant of the marine base. The speakers were:

Dr. Harry H. Wilson, Los Angeles, Greetings from the State Medical Association.

Dr. Philip K. Gilman, San Francisco, Status of Medical Preparedness in California.

Lieut. Col. Bert S. Thomas, Sacramento, Selective Service Plans in California.

Capt. William L. Mann, Combined Operations of Naval Medical Department Unit with Land and Sea Forces.

Capt. Griffith E. Thomas, The Medical Side of Naval Recruit Training.

Capt. Frederic L. Conklin, Surgery in Modern Warfare.

Comdr. Louis H. Roddis, The Training of Hospital Corpsmen in the Navy.

Comdr. Joel J. White, Some Aspects of Aviation Medicine.

Comdr. Eugene L. Walter, The Dental Side of Naval Recruit Training.

Lieut. Comdr. John F. Luten, Venereal Diseases and National Defense.

MEETINGS OF INDUSTRIAL HYGIENISTS

The annual meeting of the National Conference of Governmental Industrial Hygienists will be held in Bethesda, Md., February 17-18 rather than in May in order to develop a coordinated industrial hygiene program for defense industries. The conference will discuss ways in which the state industrial hygiene units, the Division of Industrial Hygiene and the Subcommittee on Industrial Health and Medicine can cooperate most effectively in maintaining and improving the health of employees in industries producing materials essential to the national defense.

The Rocky Mountain Industrial Hygienists will hold a conference in Idaho Falls, Idaho, the early part of February, for the purpose of discussing industrial hygiene problems, especially as they relate to national defense. Representatives from Utah, Colorado, Wyoming, Montana and Idaho will participate in the conference.

NURSES NEEDED FOR IMMEDIATE ASSIGNMENT

The War Department has announced that three hundred and twenty-five nurses are needed for assignment by February 15 to staff the hospital at the following training centers, which will be occupied by troops by the early part of March:

Fort Devens, Mass., First Division, Regular Army, one hundred and twenty nurses.

Indiantown Gap Military Reservation, Pa., Twenty-Eighth Division, Pennsylvania National Guard, eighty-five nurses.

Camp Forrest, Tenn. (formerly Camp Peay), Thirty-Third Division, Illinois National Guard, one hundred and twenty nurses.

LIBRARY ON MILITARY MEDICINE PRESENTED TO YALE

Dr. John F. Fulton, Sterling professor of physiology, Yale University School of Medicine, New Haven, Conn., has presented to the Yale Medical Library a collection of all books and government documents bearing on military medicine published in England since the beginning of the war. There are about fifty items in the group plus a collection of all the reports of the Medical Research Council on various phases of industrial medicine. In the latter series there are about seventy titles. The collection is now available in the new Reading Room of the General Medical Library in the Sterling Hall of Medicine.

PHARMACEUTICALS TO BRITAIN

The Western New York branch of the American Pharmaceutical Association recently conducted a campaign to collect drugs and medicinal preparations to send to England. Donations included one million aspirin tablets from one manufacturer, 7,500 tablets of sulfanilamide from another, varying amounts of vitamin preparations and supplies such as gauze, adhesive tape, hypodermic needles, cotton, rubber gloves and antiseptics. Pharmacy students at the University of Buffalo collected the donations as their contribution to the campaign.

LITERATURE ON MILITARY MEDICINE

The library of the Medical Society of the County of Kings, New York, has compiled a list of its publications on military, naval and aviation medicine. The list includes more than fifty books, manuals, pamphlets and reprints. In addition, the library keeps on file a number of current periodicals devoted wholly or partly to military medicine.

MORE HOSPITAL FACILITIES AT FORT SHERIDAN

The War Department authorized, January 7, the construction of additional hospital facilities at Fort Sheridan, Illinois, which will provide from one hundred and eighty-four to two hundred and sixty-nine additional beds and cost about \$295,500.

LECTURES ON MEDICAL PREPAREDNESS

The Philadelphia County Medical Society has begun its second series of lectures on medical preparedness, arranged by the committee on national defense. At the first meeting, January 30, Drs. Baldwin L. Keyes and Edmund B. Spaeth discussed "Malingering" from the point of view of the psychiatrist and the ophthalmologist respectively. The committee plans to arrange monthly lectures.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY

THIRD CORPS AREA

The following additional medical reserve corps officers had been ordered to extended active duty by the Commanding General, Third Corps Area, up to January 24. The Third Corps Area comprises the states of Pennsylvania, Virginia, District of Columbia and Maryland.

BOWERS, George Steel, 1st Lieut., Rustburg, Va., Fort George G. Meade, Md.
CHALFANT, Chads Owen, 1st Lieut., Donora, Pa., Fort Belvoir, Va.
ENGLEHART, Charles Edward, Captain, Edgewood, Pa., Fort Myer, Va.
FERKANY, Joseph Ernest, 1st Lieut., McKees Rocks, Pa., Fort McClellan, Ala.
JAVOIS, Alexander John, Captain, Pittsburgh, Camp Lee, Va.
JENNINGS, Edward Clifford, 1st Lieut., Washington, D. C., Indiantown Gap, Pa.
KEITHAN, John Frederick, 1st Lieut., Doylestown, Pa., Camp Lee, Va.

LEONE, Peter Pascal, 1st Lieut., Philadelphia, Camp Blanding, Fla.
MCGILL, John Francis, 1st Lieut., Pittsburgh, Camp Shelby, Miss.
McLANE, Charles Francis, Jr., 1st Lieut., South Williamsport, Pa., Camp Lee, Va.
McNELLIE, William Owen, 1st Lieut., Pittsburgh, Camp Blanding, Fla.
MESSER, William Allison, Captain, Pittsburgh, Fort George G. Meade, Md.
ORLEANS, Harry Byron, Captain, Washington, D. C., Fort Belvoir, Va.
PEACOCK, John Howell, Jr., 1st Lieut., Washington, D. C., Fort Belvoir, Va.
POHL, Charles Matthew, 1st Lieut., Manheim, Pa., Edgewood Arsenal, Md.
SMITH, John Prinz, 1st Lieut., Baltimore, Camp Lee, Va.
SOMMERS, Elmo Bauer, 1st Lieut., Norristown, Pa., Camp Blanding, Fla.
WHITLEY, Ayer Crouch, Captain, Palmyra, Va., Camp Shelby, Miss.
WOODWARD, Theodore Englar, 1st Lieut., Westminster, Md., Fort George G. Meade, Md.

FOURTH CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Fourth Corps Area, since January 17. The Fourth Corps Area comprises the states of Tennessee, North Carolina, South Carolina, Alabama, Georgia, Mississippi, Florida and Louisiana.

BATES, Thomas H., Major, Lake City, Fla., Fort Benning, Ga.
CAMP, Benjamin L., Captain, Ellijay, Ga., Fort Bragg, N. C.
CARTER, Harvey W., 1st Lieut., Murfreesboro, Tenn., Fort Sam Houston, Texas.
COLLUM, Tillman B., 1st Lieut., Golden, Miss., Fort Benning, Ga.
COUSAR, John B., 1st Lieut., Bishopville, S. C., Fort Jackson, S. C.
CULLIPHER, Edward W., Captain, Miami, Fla., Fort Benning, Ga.
DuBARD, Horton G., 1st Lieut., Knoxville, Tenn., Camp Peay, Tenn.
ELLIOTT, John L., Captain, Savannah, Ga., Fort Benning, Ga.
FARRER, Frederick E., 1st Lieut., Miami, Fla., Camp Wheeler, Ga.
FELDER, George D., Major, New Orleans, Fort Benning, Ga.
GORMAN, John M., Major, Jacksonville, Fla., Fort Benning, Ga.
JAMES, Samuel W., 1st Lieut., Ackernau, Miss., Fort Benning, Ga.
KENDRICK, Odis G., Major, Tallahassee, Fla., Fort Benning, Ga.
KENNEDY, David W., 1st Lieut., Vivian, La., Fort Bragg, N. C.
KINNARD, George P., Major, Newman, Ga., Fort Benning, Ga.
LEA, Joseph D., 1st Lieut., Baton Rouge, La., Camp Claiborne, La.

LIPSCOMB, James E., Jr., 1st Lieut., Greenville, S. C., Fort Bragg, N. C.
MANASCO, Hobson, 1st Lieut., Carbon Hill, Ala., Camp Croft, S. C.
McDANIEL, Thomas F., 1st Lieut., Sanford, Fla., Fort Benning, Ga.
McELHENY, Franklin, 1st Lieut., Miami, Fla., Fort Bragg, N. C.
MORIN, Henri G., 1st Lieut., St. Petersburg, Fla., Fort Benning, Ga.
NEUFFER, Frank H., 1st Lieut., Atlanta, Ga., Fort Benning, Ga.
PROVOST, Edwin K., 1st Lieut., Nashville, Tenn., Fort Benning, Ga.
QUANTZ, Herman C., 1st Lieut., Shreveport, La., Fort Benning, Ga.
RAINES, Hugh R., Major, Memphis, Tenn., Fort Benning, Ga.
ROSENBAUM, Maurice M., Captain, Shalotte, N. C., Fort Sam Houston, Texas.
SHERMAN, Kenneth G., Captain, Biloxi, Miss., Camp Davis, N. C.
SMITH, George C., 1st Lieut., Florence, S. C., Camp Peay, Tenn.
SNEED, Ralph, 1st Lieut., Jackson, Miss., Camp Davis, N. C.
TATUM, Walter L., Lieut. Col., Salisbury, N. C., Fort Benning, Ga.
WARD, Albert L., 1st Lieut., Fort St. Joe, Fla., Fort Benning, Ga.
WEINSTEIN, Howard I., 1st Lieut., Sumter, S. C., Fort Benning, Ga.
WILSON, Samuel A., 1st Lieut., Lincolnton, N. C., Camp Beauregard, La.

Relieved from Duty

The following officers, previously reported, have been relieved from duty or their orders have been revoked:

HIGHTOWER, Jesse R., 1st Lieut., Ita Bena, Miss.
NORMENT, Robert L., 1st Lieut., Lumberton, N. C.

SIXTH CORPS AREA

The following additional medical reserve officers had been ordered to extended active duty by the Commanding General, Sixth Corps Area, up to January 24. The Sixth Corps Area comprises the states of Wisconsin, Illinois and Michigan.

BAUER, Gerhard H., 1st Lieut., Ann Arbor, Mich., 5th Division, Fort Custer, Mich.
BOUYER, Harsba F., 1st Lieut., Chicago, 184th Field Artillery, Fort Custer, Mich.
BRISTOW, Jack H., 1st Lieut., Monroe, Wis., 5th Division, Fort Custer, Mich.
BROWN, King D., Captain, Chicago, 184th Field Artillery, Fort Custer, Mich.
BROWN, Marion G., 1st Lieut., Detroit, 38th Infantry, Fort Sam Houston, Texas.
BROWNS, Herschel L., 1st Lieut., Ann Arbor, Mich., Medical Supply Depot, Fort Sam Houston, Texas.
CALLAHAN, George B., Captain, Waukegan, Ill., 2d Medical Laboratory, Fort Sam Houston, Texas.
CAMPBELL, William J., 1st Lieut., Detroit, Medical Supply Depot, Fort Sam Houston, Texas.
COOK, James C., 1st Lieut., Detroit, Station Hospital, Fort Custer, Mich.
CROSS, Kenneth R., 1st Lieut., Detroit, 5th Division, Fort Custer, Mich.
CROUT, George T., Captain, Flanagan, Ill., 2d Medical Laboratory, Fort Sam Houston, Texas.
DEUTERMAN, Joel L., Captain, Elgin, Ill., Station Hospital, Camp Grant, Ill.
DOUD, Ernest A., 1st Lieut., Chicago, 5th Division, Fort Custer, Mich.
FINKLE, John R., Major, Plainfield, Ill., 77th Field Artillery, Fort D. A. Russell, Wyo.
GARLAND, John C., Captain, Mount Carroll, Ill., Medical Supply Depot, Fort Sam Houston, Texas.
GORDON, Orville E., 1st Lieut., Chicago, 5th Division, Fort Custer, Mich.
GUZZETTA, Marcus M., 1st Lieut., Milwaukee, Medical Supply Depot, Fort Sam Houston, Texas.
HESOG, Paul, 1st Lieut., Kenosha, Wis., 1st Medical Squadron, Fort Bliss, Texas.

HOERNESCHMEYER, Joseph L., Captain, Granite City, Ill., 2d Medical Laboratory, Fort Sam Houston, Texas.
HOUSTON, William H., 1st Lieut., Ann Arbor, Mich., 1st Medical Squadron, Fort Bliss, Texas.
IMMERMAN, Harold M., 1st Lieut., Saginaw, Mich., 2d Medical Battalion, Fort Sam Houston, Texas.
KAISER, Lloyd F., 1st Lieut., Rhinelander, Wis., Medical Supply Depot, Fort Sam Houston, Texas.
KEHL, Sylvester C., Major, Chicago, Medical Supply Depot, Fort Sam Houston, Texas.
KINGSBURY, Charles H., 1st Lieut., Goodman, Wis., 1st Medical Squadron, Fort Bliss, Texas.
KNAPP, Howard C., Captain, Belleville, Ill., 2d Medical Laboratory, Fort Sam Houston, Texas.
KNEWITZ, Ralph W., Captain, East St. Louis, Ill., 12th Cavalry, Fort Ringgold, Texas.
KNUTSON, Lewis A., 1st Lieut., Westby, Wis., 1st Medical Squadron, Fort Bliss, Texas.
KRETLOW, Fred A., 1st Lieut., Chicago, 1st Medical Squadron, Fort Bliss, Texas.
LEPAK, Alfred J., 1st Lieut., Chicago, 1st Medical Squadron, Fort Bliss, Texas.
LERNER, David, 1st Lieut., Chicago, 8th Engineers, Fort McIntosh, Texas.
LERNER, David, 1st Lieut., An Gres, Mich., 2d Medical Battalion, Fort Sam Houston, Texas.
LOCKLIN, Walter K., 1st Lieut., Ann Arbor, Mich., 2d Medical Battalion, Fort Sam Houston, Texas.
MacDONALD, Hugh, Captain, Skokie, Ill., 2d Medical Laboratory, Fort Sam Houston, Texas.
MATSON, Kenneth L., 1st Lieut., Chicago, 2d Medical Battalion, Fort Sam Houston, Texas.
MENAKER, Gerald J., 1st Lieut., Chicago, Hq. & Hq. Bn., 2d Div., Fort Sam Houston, Texas.
MITCHELL, Mancel T., 1st Lieut., Eau Claire, Wis., 38th Infantry, Fort Sam Houston, Texas.
PAISLEY, Alfred M., 1st Lieut., Jacksonville, Ill., 5th Division, Fort Custer, Mich.
PRUDOWSKY, Harry, 1st Lieut., Milwaukee, 5th Division, Fort Custer, Mich.

REGNIER, Walter O., Captain, Drummond, Wis., 12th Cavalry, Fort Ringgold, Texas.
RIGHTMAN, Bert, 1st Lieut., Chicago, 5th Division, Fort Custer, Mich.
SACHS, Mandel, 1st Lieut., Chicago, 2d Medical Battalion, Fort Sam Houston, Texas.
SALINSKY, Lester V., 1st Lieut., Sheboygan, Wis., 77th Field Artillery, Fort D. A. Russell, Wyo.
SANTORO, Antonio, Captain, Chicago, 7th Cavalry, Fort Bliss, Texas.
SCHWADE, Edward D., 1st Lieut., Shorewood, Wis., Station Hospital, Camp Grant, Ill.
SEIDMON, Edward E. P., 1st Lieut., Chicago, 2d Division Artillery, Fort Sam Houston, Texas.
SHAGAN, Robert M., 1st Lieut., Chicago, 5th Division, Fort Custer, Mich.
SHAPIRO, I. A., 1st Lieut., Detroit, 38th Infantry, Fort Sam Houston, Texas.
SHARP, Mahlon S., 1st Lieut., Detroit, 5th Division, Fort Custer, Mich.
SHULRUFF, Harry I., 1st Lieut., Chicago, Chicago Induction Board, Armory.

SMITH, James J., 1st Lieut., Chicago, 5th Division, Fort Custer, Mich.
SOROCK, Milton L., 1st Lieut., Detroit, 5th Division, Fort Custer, Mich.
STEIN, Albert F., 1st Lieut., Chicago, 5th Division, Fort Custer, Mich.
STERN, Louis S., Captain, West Allis, Wis., 7th Cavalry, Fort Bliss, Texas.
SULLENBERGER, Neil H., 1st Lieut., Detroit, 2d Medical Battalion, Fort Sam Houston, Texas.
TURNBULL, George C., Captain, Evanston, Ill., 82d Field Artillery, Fort Bliss, Texas.
WAGNER, David, Captain, Chicago, 77th Field Artillery, Fort D. A. Russell, Wyo.
WALLACE, John K., II, 1st Lieut., Marion, Ill., 5th Medical Battalion, Fort Custer, Mich.
WALSKE, Benedict R., 1st Lieut., Independence, Wis., Station Hospital, Camp Grant, Ill.
WEAVER, David F., 1st Lieut., Green Bay, Wis., 38th Infantry, Fort Sam Houston, Texas.
YELLEN, Harry J., 1st Lieut., Chicago, 77th Field Artillery, Fort D. A. Russell, Wyo.

SEVENTH CORPS AREA

The following additional medical reserve officers have been ordered to extended active duty by the Commanding General, Seventh Corps Area, up to January 11. The Seventh Corps Area comprises the states of North Dakota, South Dakota, Minnesota, Nebraska, Iowa, Kansas, Missouri, Arkansas and Wyoming.

ALLEN, Willi, n Edward, Jr., Captain, St. Louis, Fort Devens, Mass.
BARRY, Gerald Williams, 1st Lieut., Kansas City, Mo., Fort Ord, Presidio of Monterey, Calif.
BJORK, Floyd Joseph, 1st Lieut., Keota, Iowa, Fort Sam Houston, Texas.
BORGMEYER, Henry John, 1st Lieut., Dodge, Neb., Camp Joseph T. Robinson, Ark.
BRANCH, James W., 1st Lieut., Hope, Ark., Fort Knox, Ky.
BREWER, William McKelvey, 1st Lieut., Hays, Kan., Camp Murray, Wash.
BRILLHART, Everett Guy, 1st Lieut., Shelby, Neb., Camp Joseph T. Robinson, Ark.
BROBYN, Thomas Elmer, Captain, Grinnell, Iowa, Fort Ord, Presidio of Monterey, Calif.
BROTT, Clarence Raymond, 1st Lieut., Jansen, Neb., Fort Leonard Wood, Mo.
BROWN, Andrew Porter, 1st Lieut., Salina, Kan., Fort Riley, Kan.
CAMPBELL, James Holmes, 1st Lieut., Joiner, Kan., Fort Ord, Presidio of Monterey, Calif.
CHRISTIANSEN, Harold August, 1st Lieut., Jamestown, N. D., Fort Ord, Presidio of Monterey, Calif.
COLLINS, Leigh George, 1st Lieut., West Point, Neb., Fort Ord, Presidio of Monterey, Calif.
CRAWFORD, William Henry, Major, Omaha, Fort Ord, Presidio of Monterey, Calif.
CUSHING, Robert Louis, 1st Lieut., Fort Scott, Kan., Fort Ord, Presidio of Monterey, Calif.
DECKER, Charles Edward, 1st Lieut., Davenport, Iowa, Camp Murray, Wash.
DEUTCH, Max, Captain, St. Louis, Camp Murray, Wash.
DEYOUNG, George Marion, 1st Lieut., George, Iowa, Camp Murray, Wash.
DILLARD, James Robert, Major, Fargo, N. D., Fort Ord, Presidio of Monterey, Calif.
EATON, Wilbur Smith, 1st Lieut., Plattsmouth, Neb., Fort Crook, Neb.

EDWARDS, Thomas Franklin, Captain, Bismarck, N. D., Fort Ord, Presidio of Monterey, Calif.
ENTRINGER, Albert Joseph, 1st Lieut., Dubuque, Iowa, Camp Murray, Wash.
FELLMAN, Abe C., 1st Lieut., Omaha, Camp Murray, Wash.
GIFFORD, Byron Lee, 1st Lieut., Long Prairie, Minn., Camp Murray, Wash.
GRAUL, Elmer George, 1st Lieut., St. Louis, Camp Murray, Wash.
GRIMES, Henry Burton, Major, Madelia, Minn., Fort Ord, Presidio of Monterey, Calif.
HAMILTON, Benjamin C., Major, Jefferson, Iowa, Camp Murray, Wash.
HELPERY, John Kenneth, 1st Lieut., Tracy, Minn., Fort Ord, Calif.
JOHNSON, Charles Nelson, Major, Wichita, Kan., Fort Ord, Presidio of Monterey, Calif.
KAMISH, Robert James, 1st Lieut., Halstead, Kan., Fort Ord, Presidio of Monterey, Calif.
MCINTIRE, Landon Rolla, Captain, St. Charles, Mo., Fort Lewis, Wash.
MEYER, Jules Owens, 1st Lieut., Grand Rapids, Minn., Fort Ord, Presidio of Monterey, Calif.
OLSSON, Paul Bryant, 1st Lieut., Lexington, Neb., Fort Leavenworth, Kan.
RANSOM, Henry Robert, 1st Lieut., Grand Forks, N. D., Fort Lewis, Wash.
REED, Charles Clay, 1st Lieut., Little Rock, Ark., Jefferson Barracks, Mo.
RYDER, Frank Dell, Major, Grand Island, Neb., Fort Francis E. Warren, Wyo.
SAGI, Joseph Herman, 1st Lieut., Minneapolis, Fort Lewis, Wash.
SEASHORE, Rosel Theodore, 1st Lieut., Duluth, Minn., Fort Ord, Presidio of Monterey, Calif.
SHAW, William John, Major, Fayette, Mo., Camp Murray, Wash.
SMITH, Herman Joseph, 1st Lieut., Des Moines, Iowa, Fort Ord, Presidio of Monterey, Calif.
SNODGRASS, William A., Jr., 1st Lieut., Pine Bluff, Ark., Camp Joseph T. Robinson, Ark.
STEINBERG, Maurice M., 1st Lieut., Omaha, Fort Leavenworth, Kan.
STEWART, Donald Edward, 1st Lieut., Grand Rapids, Minn., Fort Lewis, Wash.
WATSON, Donald Paul, 1st Lieut., Grand Island, Neb., Fort Lewis, Wash.
WILLIAMS, Harold Otis, Captain, Cheney, Kan., Fort Lewis, Wash.
WYATT, Charles Arthur, Major, Holton, Kan., Fort Lewis, Wash.

REGULAR ARMY ORDERS

BOLLERUD, Jack, 1st Lieut., from Brooklyn, to Anchorage, Alaska.
FROITZHEIM, William J., Lieut. Col., from the Hawaiian Department to Fort Niagara, N. Y.
GLAUBMAN, William A., 1st Lieut., from Fort Benning, Ga., and LAWRY, Lee L., 1st Lieut., from Fort George G. Meade, Md., to the Puerto Rican Department.
HIESINGER, James D., Colonel, Fort Lewis, Wash., retired January 31 for age.

MAYFIELD, George C., Captain, from Hot Springs National Park, Ark., to Hawaiian Department.

WELLS, Francis P., Captain, from Holabird Q. M. Depot, Md., to Panama Canal Department, sailing from New York February 18.

WILLIAMSON, Carl S., Major, and MAUZERY, Armand J., 1st Lieut., from Fort Sheridan, Ill., to Puerto Rican Department.

THE 135th MEDICAL REGIMENT

The 135th Medical Regiment of the Wisconsin National Guard is now assigned as the Third U. S. Army Medical Regiment and is in camp at Camp Shelby, Miss. The following medical officers are on duty with the regiment:

BECKER, Reinhard, Major, Milwaukee.
BECKER, Walter T., Captain, Cedarburg, Wis.
BLECKWENN, William J., Colonel, Madison, Wis.
BOXER, Leo W., Captain, Milwaukee.
CHRISTIANSEN, Wilmer H., Captain, Milwaukee.
EAGLEBURGER, Leon S., Major, Waupun, Wis.
GALLOGLY, John A., 1st Lieut., Milwaukee.
HAUKOHL, Robert S., 1st Lieut., Milwaukee.

HIDDE, Frederick G., Captain, Sheboygan, Wis.
HOLMES, John F., 1st Lieut., Milwaukee.
KENDALL, Earl Thurman, Captain, Milwaukee.
LUDWIG, Erwin P., Captain, Wausau, Wis.
McMAHON, Raymond A., 1st Lieut., Madison, Wis.
MILLER, James E., Captain, Madison, Wis.
MUSSER, Marc J., Jr., Major, Madison, Wis.
PETERSON, John R., 1st Lieut., Milwaukee.
PETERSON, Leo W., Lieut. Colonel, Sun Prairie, Wis.
POHLE, Frederick J., Major, Madison, Wis.
SCHWARZE, Cyril A., 1st Lieut., Watertown, Wis.
THANOS, John N., 1st Lieut., Milwaukee.
VETTER, Edward W., Captain, Stevens Point, Wis.
WEISSMILLER, Lester L., Captain, Madison, Wis.
WILKINSON, Philip M., Captain, Oconomowoc, Wis.

ORGANIZATION SECTION

THE PHYSICIANS FEDERAL INCOME TAX—1941

PREPARED BY THE BUREAU OF LEGAL MEDICINE AND LEGISLATION

Every one who is required to make a federal income tax return must do so on or before March 15, unless an extension of time for filing his return has been granted. For cause shown, the collector of internal revenue for the district in which the taxpayer files his return may grant such an extension, on application filed with him by the taxpayer. This application must state fully the causes for the delay. Failure to make a return may subject the taxpayer to a penalty of 25 per cent of the amount of the tax due.

The normal rate of tax on residents of the United States and on all citizens of the United States regardless of their places of residence is 4 per cent on net income in excess of the exemptions and credits. The Revenue Act of 1940 imposes an additional tax, designated as a defense tax, which in general adds 10 per cent to the amount of tax a person otherwise would be required to pay.

Attention again is called to the provisions of the Public Salary Tax Act of 1939, which subjects to the federal income tax laws the income derived from personal services rendered as an officer or employee of a state, political subdivision, or any agency or instrumentality of either. Theretofore, such income had been considered nontaxable under the federal income tax laws if received for services rendered in carrying out a governmental function. Furthermore, the federal government, under that act, consented to the taxation of states by local taxing authorities of compensation received for personal service as an officer or employee of the United States, any territory or possession or political subdivision, the District of Columbia or any agency or instrumentality of any one or more of the foregoing, if such taxation does not discriminate against such officer or employee because of the source of such compensation. In effect, this act does away with the immunity from federal income taxes theretofore accorded employees of states, their political subdivisions, agencies or instrumentalities and the immunity from state and local taxes of the income received by federal officers or employees.

WHO MUST FILE RETURNS

1. Returns must be filed by every unmarried person and by every married person not living with spouse, if gross income during 1940 was \$800 or more.

2. Returns must be filed by every married person who lived with spouse, if gross income during 1940 was \$2,000 or over. If both husband and wife had income and their combined gross income was \$2,000 or over, they must either file separate returns or, if both are citizens or residents of the United States and if they were living together at the end of the taxable year, they may file a joint return. If a person was married and lived with spouse for only part of 1940, special rules apply with respect to the filing of returns, and physicians who come within this classification should read carefully the instructions given on the tax return blanks.

If the status of a taxpayer, so far as it affects the personal exemption or credit for dependents, changed during the year, the personal exemption and credit must

be apportioned, under rules and regulations prescribed by the Commissioner of Internal Revenue with the approval of the Secretary of the Treasury, in accordance with the number of months before and after such change. For the purpose of such apportionment a fractional part of a month should be disregarded unless it amounts to more than half a month, in which case it is to be considered as a month.

As a matter of courtesy only, blanks for returns are sent to taxpayers by the collectors of internal revenue, without request. Failure to receive a blank does not excuse any one from making a return; the taxpayer should obtain the necessary blank from the local collector of internal revenue.

The following discussion covers only matters relating specifically to physicians. Full information concerning questions of general interest may be obtained from the official return blank and from the collectors of internal revenue.

GROSS AND NET INCOMES: WHAT THEY ARE

Gross Income.—A physician's gross income is the total amount of money received by him during the year for professional services, regardless of the time when the services were rendered for which the money was paid, plus such money as he has received as profits from investments and speculation and as compensation and profits from other sources.

Net Income.—Certain professional expenses and the expenses of carrying on any enterprise in which the physician may be engaged for gain may be subtracted as "deductions" from the gross income, to determine the net income on which the tax is to be paid. An "exemption" is allowed, the amount depending on the taxpayer's marital status during the tax year as stated before. These matters are fully covered in the instructions on the tax return blanks.

Earned Income.—In computing the normal tax, but not the surtax, there may be subtracted from net income from all sources an amount equal to 10 per cent of the earned net income, except that the amount so subtracted shall in no case exceed 10 per cent of the net income from all sources. Earned income means professional fees, salaries and wages received as compensation for personal services, as distinguished from receipts from other sources.

The first \$3,000 of a physician's net income from all sources may be regarded under the law as earned net income, whether it was or was not in fact earned within the meaning set forth in the preceding paragraph. Net income in excess of \$3,000 may not be claimed as earned unless it in fact comes within that category. No physician may claim as earned net income any income in excess of \$14,000.

DEDUCTIONS FOR PROFESSIONAL EXPENSES

A physician is entitled to deduct all current expenses necessary in carrying on his practice. The taxpayer should make no claim for the deduction of expenses unless he is prepared to prove the expenditure by competent evidence. So far as practicable, accurate itemized records should be kept of expenses and substantiating

evidence should be carefully preserved. The following statement shows what such deductible expenses are and how they are to be computed:

Office Rent.—Office rent is deductible. If a physician rents an office for professional purposes alone, the entire rent may be deducted. If he rents a building or apartment for use as a residence as well as for office purposes, he may deduct a part of the rental fairly proportionate to the amount of space used for professional purposes. If the physician occasionally sees a patient in such dwelling house or apartment, he may not, however, deduct any part of the rent of such house or apartment as professional expense; to entitle him to such a deduction he must have an office there, with regular office hours. If a physician owns the building in which his office is located, he cannot charge himself with "rent" and deduct the amount so charged.

Office Maintenance.—Expenditures for office maintenance, as for heating, lighting, telephone service and the services of attendants, are deductible.

Supplies.—Payments for supplies for professional use are deductible. Supplies may be fairly described as articles consumed in the using; for instance, dressings, clinical thermometers, drugs and chemicals. Professional journals may be classified as supplies and the subscription price deducted. Amounts currently expended for books, furniture and professional instruments and equipment, "the useful life of which is short," generally less than one year, may be deducted; but if such articles have a more or less permanent value, their purchase price is a capital expenditure and is not deductible.

Equipment.—Equipment comprises property of a more or less permanent nature. It may ultimately wear out, deteriorate or become obsolete, but it is not in the ordinary sense of the word "consumed in the using."

The cost of equipment, such as has been described, for professional use, cannot be deducted as expense in the year acquired. Examples of this class of property are automobiles, office furniture, medical, surgical and laboratory equipment of more or less permanent nature, and instruments and appliances constituting a part of the physician's professional outfit, to be used over a considerable period of time, generally over one year. Books of more or less permanent nature are regarded as equipment and the purchase price is therefore not deductible.

Although the cost of such equipment is not deductible in the year acquired, nevertheless it may be recovered through depreciation reductions taken year by year over its useful life, as described later.

No hard and fast rule can be laid down as to what part of the cost of equipment is deductible each year as depreciation. The amount depends to some extent on the nature of the property and on the extent and character of its use. The length of its useful life should be the primary consideration. The most that can be done is to suggest certain average or normal rates of depreciation for each of several classes of articles and to leave to the taxpayer the modification of the suggested rates as the circumstances of his particular case may dictate. As fair, normal or average rates of depreciation, the following have been suggested: automobiles, 25 per cent a year; ordinary medical libraries, x-ray equipment, physical therapy equipment, electrical sterilizers, surgical instruments and diagnostic apparatus, 10 per cent a year; office furniture, 5 per cent a year.

The principle governing the determination of all rates of depreciation is that the total amount claimed by the taxpayer as depreciation during the life of the article, plus the salvage value of the article at the end of its useful life, shall not be greater than its purchase price or, if purchased before March 1913, either its fair market value as of that date or its original cost, whichever may be greater. The physician must in good faith use his best judgment and claim only such allowance for depreciation as the facts justify. The estimate of useful life, on which the rate of depreciation is based, should be carefully considered in his individual case.

In a Treasury Decision, approved Feb. 28, 1934, No. 4422, it was held, among other things, that:

1. The cost to be recovered shall be charged off over the useful life of the property.

2. The reasonableness of any claim for depreciation shall be determined on the conditions known to exist at the end of the period for which the return was made.

3. Where the cost or other basis of the property has been recovered through depreciation or other allowances, no further deduction for depreciation shall be allowed.

4. The burden of proof will rest on the taxpayer to sustain the deduction claimed.

5. The deduction for depreciation in respect to any depreciable property for any taxable year shall be limited to such ratable amount as may reasonably be considered necessary to recover during the remaining life of the property the unrecovered cost or other basis.

Particular attention is called to the last of the foregoing provisions. If, in prior years, rates have been claimed which, if continued, will fully depreciate the cost, less salvage, before the end of its useful life, based on conditions now known, a reestimate of the remaining useful life should now be made and the portion of the cost that had not been depreciated at the beginning of the year 1940 (for a return for the year 1940) should be spread over this reestimated life.

Medical Dues.—Dues paid to societies of a strictly professional character are deductible. Dues paid to social organizations, even though their membership is limited to physicians, are personal expenses and not deductible.

Postgraduate Study.—The Commissioner of Internal Revenue holds that the expense of postgraduate study is not deductible.

Traveling Expenses.—Traveling expenses, including amounts paid for transportation, meals and lodging, necessarily incurred in professional visits to patients and in attending medical meetings for a professional purpose, are deductible.

Automobiles.—Payment for an automobile is a payment for permanent equipment and is not deductible. The cost of operation and repair, and loss through depreciation, are deductible. The cost of operation and repair includes the cost of gasoline, oil, tires, insurance, repairs, garage rental (when the garage is not owned by the physician), chauffeurs' wages, and the like.

Deductible loss through depreciation of an automobile is the actual diminution in value resulting from obsolescence and use and from accidental injury against which the physician is not insured. If depreciation is computed on the basis of the average loss during a series of years, the series must extend over the entire estimated life of the car, not merely over the period in which the car is possessed by the present taxpayer.

psychotherapy, chromotherapy, zone-therapy, helio-therapy, corrective and orthopedic gymnastics, external applications, manipulation, nutritional control, psychology, biochemistry, hygiene, first aid, sanitation, dietetics, mechanical and electrical appliances, herbology, massage, anatomical correction; x-ray for diagnostic purposes only, irrigations of the body orifices; and that Naturopathy and Naturopathy shall be constructed as synonymous terms. And that also Sanipractic and Drugless Physicians shall be interpreted as the same as Naturopathy and its practice, and shall hereby be governed and regulated by this Act and Chapter. Provided, however, that nothing in this chapter shall be construed or held to authorize any Naturopathic Physician licensed hereunder to use narcotic drugs or practice surgery, or Chiropraxy." S. 240 and H. 334 propose to appropriate \$210,000 for each of the fiscal years 1941-42 and 1942-43 to organize, operate and maintain local full time health services throughout the state, these amounts to be used for the specific purpose of matching on a dollar for dollar basis federal funds that are available to the Tennessee Department of Public Health through provisions of the Federal Social Security Act and other federal appropriations for public health purposes. The bills also propose to appropriate for each fiscal year noted \$50,000 to be used to provide essential and additional public health services in areas where special financial or public health problems exist, for the establishment of approved local public health services where such services do not exist as of the date either of these bills is enacted and for any other emergency or necessary public health service for which financial provisions have not been made. H. 352 and S. 277 propose to appropriate for the coming fiscal year \$175,000 to be allocated at the rate of not less than \$2,500 per annum to each county and to each of the four major city governments maintaining an approved cooperative full-time public health service to be used for the specific purpose of matching on a dollar-for-dollar basis federal or other funds that are available to the Tennessee Department of Public Health through provisions of the Federal Social Security Act and other federal or other appropriations for public health purposes. For the fiscal year beginning July 1, 1942, the amount to be appropriated is to be \$190,000. The bill also proposes to appropriate an additional \$50,000 for the next two ensuing fiscal years to be used for the purpose of providing essential public health services in areas where special financial or public health problems exist, for the establishment of approved local public health services where such services do not exist and for any other emergency or essential public health service required for the protection of the public health. H. 351 and S. 278 propose to authorize the Division of Tuberculosis Control, in making provisions for the medical and surgical care of emergency and meritorious cases among economically dependent persons, to expend an amount not to exceed 10 per cent of the total funds available for hospitalization at a rate not to exceed \$2.50 per patient per diem without an equal matching requirement from counties or municipalities. H. 425 and S. 315, to amend the medical practice act, propose (1) to eliminate that provision in the present law that requires four members of the medical examining board to be nonsectarian physicians, one member to be a homeopath and one member to be an eclectic, and (2) to set the fee for the issuance of a license by reciprocity at \$50.

Utah

Bills Introduced.—S. 43, to amend the chiropraxy practice act, proposes that an applicant for a license to practice chiropraxy must either (1) have completed two years in a recognized college of liberal arts, and must be a graduate of a regularly established school of chiropraxy as recognized by the National Association of Chiropraxists, which requires as a prerequisite to graduation the completion of three chiropraxical-podiatric terms of at least three thousand, one hundred and twenty hours of class work given over a period of not less than three different calendar years; or (2) have completed one year in a recognized college of liberal arts or of the sciences and have graduated from a regularly established school of chiropraxy as recognized by the National Association of Chiropraxists, which requires as a prerequisite to graduation the completion of four chiropraxical-podiatric terms of at least four thousand, one hundred and sixty hours of class work given over a period of not less than four different calendar years. S. 12, to supplement the laws relating to the practice of the healing arts, proposes to authorize the issuance of the following additional classes of licenses to practice the healing arts: (1) "To practice as a naturopathic physician without the use of drugs and without operative surgery in accordance with the tenets of a professional school of naturopathy recognized by the department of registration" and (2) "To practice as a naturopathic physician and surgeon in accordance with the tenets of a professional school of naturopathy recognized by the department of registration, and having had class work equal to the standard of other practitioners of surgery." S. 13, to amend the law relating to the practice of dentistry, proposes to authorize the revocation or suspension of a licensee: (1) "Advertising his dental business or treatment or devices by untruthful, improbable or impossible statements, or advertising in any manner except by the use of newspapers, periodicals, signs, cards, radio and other lawful means of advertising, provided, that definite fixed prices or charges to be made be advertised in the manner and by the means hereinabove specified, and provided further that advertising in any manner or by any means whatsoever as in this act provided, shall be only in the name of the licensed dentist," and (2) "Failing to keep his price list of all dental operations of both minimum and maximum prices in a conspicuous place in his reception room, and at each dental chair in his dental office; The price list shall be in letters not smaller than one inch in size, and if the dentist employs a commercial dental laboratory to do his prosthetic work, price list of said laboratory shall be attached thereto." S. 59 proposes to transfer the enforcement of the uniform narcotic drug act and of the prophylactic act from the Department of Registration to the Board of Pharmacy. S. 67 proposes to enact a so-called occupational disease disability compensation act and to authorize the recovery of compensation by any employee who sustains from his employment one or more of the twenty-seven occupational diseases enumerated in the bill. S. 93, to amend the sales tax law, proposes to levy a tax of 2 per cent on the amount paid to any person for professional services rendered. S. 102 proposes to enact what it cites as the Food, Drug and Cosmetic Act to regulate the manufacture, sale, distribution or advertising of foods, drugs, cosmetics and therapeutic devices.

OFFICIAL NOTES

Hotels in Cleveland

On advertising page 46 of this issue of THE JOURNAL may be found a table containing a list of hotels in Cleveland and rates for rooms.

The form printed in the advertising pages may be clipped and, when it has been properly filled in, should be sent at once to Dr. Edward F. Kieger, Chairman, Subcommittee on Hotels of the Local Committee on Arrangements, Cleveland Convention and Visitors' Bureau, Incorporated, 1604 Terminal Tower, Cleveland, Ohio.

RADIO BROADCASTS

The next three programs to be broadcast in the series Doctors at Work are as follows:

- February 12. Medical Detective.
- February 19. One Man's Poison.
- February 26. Exploring Man's Mind.

The program is scheduled over the Blue network of the National Broadcasting Company Wednesdays at 10:30 p. m. eastern standard time (9:30 central, 8:30 mountain, 7:30 Pacific time).

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Personal.—Dr. Julius A. Katzive, assistant director of the Mount Sinai Hospital of New York for several years, has been appointed superintendent of the Mount Zion Hospital of San Francisco.

Hospital Conference.—Dr. Cyrus C. Sturgis, professor of internal medicine, University of Michigan Medical School, Ann Arbor, was the guest speaker of the San Jose Hospital Association at its conference January 6-10. Dr. Sturgis's subjects were the nature and treatment of hypertension, the hemorrhagic diseases, the menace and treatment of obesity, the macrocytic anemias and the anemias of pregnancy, and the therapeutic value of blood transfusions, preserved blood and blood substitutes.

Society News.—The Alameda County Medical Association was addressed January 20 by William H. Hollander, Oakland attorney, on "The Fifth Column Menace in America." Drs. Lloyd F. Hawkinson, Oakland, and Adelbert M. Moody, San Francisco, presented a symposium on basal metabolism. The Los Angeles Society of Neurology and Psychiatry was addressed, January 15, by Drs. Hans V. Briesen on "Neurosurgical Consideration of Spinal Canal Impingement by Hypertrophied Ligamenta Flava and Protruded Intervertebral Disks" and George Mosser Taylor, "Clinical Experience with the Sciatic Syndrome."

COLORADO

The Sewall Lectures.—Dr. Cyrus C. Sturgis, professor of internal medicine, University of Michigan Medical School, Ann Arbor, will deliver the Henry Sewall Memorial Lectures at the University of Colorado School of Medicine, Denver. His subject on February 11 will be "The Therapeutic Value of Blood and Blood Substitutes" and on February 13 "The Hemorrhagic Diseases."

CONNECTICUT

Waterbury Forms a Health Council.—A health council comprising representatives of medical, dental, civic and other agencies has been formed in Waterbury. The purpose of the council, which is an outgrowth of the Waterbury Citizens' Advisory Committee on Health, will be, among other things, to develop a cooperative program with all community public health agencies. The establishment of the council was urged in a recommendation following a public health survey made in 1939 by Ira V. Hiscock, C.P.H., and associates of the department of public health of Yale University School of Medicine, New Haven.

DISTRICT OF COLUMBIA

Society News.—The Washington Urological Society will be addressed by Dr. Stanford W. Mulholland, Philadelphia, February 19, on "Hypertension with Unilateral Renal Disease."

—The Medical Society of the District of Columbia will be addressed, February 26, by Drs. Arthur M. Grossman on "Practical Therapy with Vitamin K"; Norman H. Jolliffe, New York, "Newer Knowledge of the Vitamin B Complex," and H. Trendley Dean, D.D.S., "Some Recent Findings with Respect to Dental Caries."

New Health Center.—The new Southwest Health Center was opened for inspection by the District health department on December 18. The three story building, which cost \$200,000, contains a laboratory and maternal and child welfare, social, chest and dental clinics. Dr. Charles B. Campbell, Washington, chairman of the health committee of the Federation of Citizens' Associations, delivered the invocation. Dr. George C. Ruhland, Washington, District health officer, was presented with a certificate of merit by the Southwest Citizens' Association.

IDAHO

Hospital News.—The new Gritman Memorial Hospital was opened at Moscow recently at a cost of \$105,000. The three story building was financed by contributions from local citizens as a memorial to the late Dr. Charles L. Gritman. Two

floors have been added to the original wing of St. Joseph's Hospital, Lewiston. Lakeside Hospital, Coeur d'Alene, has recently increased its capacity from fifteen to thirty-five beds.

ILLINOIS

Personal.—Lieut. Marcus D. Burnstine, Columbus, Ohio, medical reserve officer, has been named physician in charge of the health service station for civilian employees at the Rock Island Arsenal, succeeding Dr. Roderick G. St. Pierre, Rock Island, who went to Portland, Ore.

Resident in Otolaryngology.—The position of junior resident in otolaryngology has become vacant at the Illinois Charitable Eye and Ear Infirmary. Applications should be addressed to Dr. Joseph C. Beck, assistant dean of instruction at the infirmary, 904 West Adams Street, Chicago.

Hospital News.—The Clara A. Abbott trust has given \$40,000 to the Evanston Hospital, supplementing an earlier donation of \$250,000. The money is being used for construction of the Abbott Memorial Building at the hospital, which will house clinical and research laboratories, an auditorium for medical teaching and facilities for outpatient diagnostic tests. Mrs. Abbott was the widow of Dr. Wallace C. Abbott, founder of the Abbott Laboratories.

CHICAGO

Annual Meeting of Heart Association.—Lieut. Col. Charles G. Hutter, Medical Corps, U. S. Army, liaison officer of the Office of the Surgeon General to the American Medical Association, will be the principal speaker and guest of honor at the annual session of the Chicago Heart Association in Abbott Hall February 12. Colonel Hutter's subject will be "Heart Disease and National Defense."

South Side Medical Assembly.—The midwinter meeting of the South Side Medical Assembly will be held on February 19 with clinics in the morning at various hospitals and afternoon and evening sessions at the Shoreland Hotel. Symposiums will make up the afternoon program, and after dinner Dr. James R. Bloss, Huntington, W. Va., will speak on "Sterility Studies in the Female." The assembly is an organization consisting of all the south side branches of the Chicago Medical Society.

Dr. Joseph Brennemann Retires.—After serving three years beyond the retirement age, Dr. Joseph Brennemann resigned, January 1, as chief of staff of the Children's Memorial Hospital, a position he had occupied since 1921. He has been succeeded by Dr. Charles Anderson Aldrich, a member of the staff for twenty years. Born in Peru, Ill., in 1872, Dr. Brennemann graduated at Northwestern University Medical School in 1900. He has been professor of pediatrics at the University of Chicago, the School of Medicine, since 1921.

INDIANA

Medical History.—Plans are under way to compile a history of medicine in Indiana. Members of the profession are urged to send in suggestions or any material they may have available to Miss Ruth McNutt, librarian, Indiana University School of Medicine, Medical Center, 1040 West Michigan Street, Indianapolis. Miss McNutt will file the material for later use by the Indiana Association for the History of Medicine.

Dr. Shanklin Honored.—Dr. Eldridge M. Shanklin, Hammond, for twenty-five years secretary of the Lake County Medical Society, was voted honorary membership in the society "for long and distinguished service" at a meeting, January 10. This is the first time in forty-three years that the society has conferred such an honor. Dr. Shanklin ended his twenty-fifth year as secretary of the society in 1938. He was president in 1920. He also served as president of the Indiana State Medical Association in 1925. Dr. Shanklin graduated at the Medical College of Indiana, Indianapolis, in 1902. Among other offices, he has been a member of the state board of registration in medicine, serving for three years as executive officer. He has been editor of the state medical journal for nine years. Formal presentation of the honorary membership will be made on February 13.

MICHIGAN

Personal.—Dr. Martha L. Longstreet was chosen as Saginaw's "outstanding citizen for 1940" recently when she was awarded an honorary life membership in the Saginaw Chamber of Commerce. Mr. George E. Phillips, superintendent of Herman Kiefer Hospital, Detroit, for twenty-six years, died

recently.—Dr. Lloyd F. Catron, assistant professor of pathology, University of Michigan Medical School, Ann Arbor, resigned, December 31, to become pathologist and director of laboratories in the Akron (Ohio) City Hospital. Dr. Catron graduated at Rush Medical College, Chicago, in 1932.

County Society Sponsors Public Exhibit.—The Kent County Medical Society opened a health exhibit in the Grand Rapids Public Museum, January 9. The exhibit will continue for six months, the themes to be changed from time to time, covering tuberculosis, pneumonia, cancer, infantile paralysis, allergy and diabetes. The auxiliary to the county medical society is planning a display of antique medical instruments, the city health department one on public health work, and the Kent County Dental Society one on dentistry. The Women's Field Army of the American Society for the Control of Cancer is cooperating in the exhibits on cancer. Grand Rapids Junior College is lending a series of charts on anatomy to be used in connection with the exhibits. Dr. William R. Vis, Grand Rapids, is chairman of the committee in charge of the exhibit.

Annual Clinic Day.—The Mount Carmel Mercy Hospital, Detroit, conducted its annual clinic day January 29. The following program was to be presented:

Dr. Grover C. Penberthy, Detroit, Surgical Treatment of Acute Osteomyelitis Combined with the Use of Sulfonamide Compounds.

Dr. Frederick A. Collier, Ann Arbor, The Closure and Healing of Wounds.

Dr. Charles H. Slocumb, Rochester, Minn., Differential Diagnosis and Treatment of the Arthritides.

Dr. Edgar H. Norris, Detroit, New Detroit Medical Center.

Dr. George Crile Jr., Cleveland, Hyperthyroidism.

Dr. Russell L. Haden, Cleveland, Treatment of Pernicious Anemia.

Dr. Morris Edward Davis, Chicago, Uses and Abuses of Cesarean Section.

At a dinner in the evening at the Hotel Statler, Dr. Edmund D. Margrave, Royal Oak, chief of staff of the hospital, was toastmaster. The speakers included Dr. Allan W. McDonald, Detroit, president, Wayne County Medical Society; the Hon. Murray D. Van Wagoner, governor of Michigan; the Hon. George Dondero, U. S. Congressman from Michigan, and the Hon. Martin Dies, U. S. Congressman from Texas.

MINNESOTA

Dr. Beadie Retires.—Dr. William D. Beadie, who has been active in tuberculosis work in Minnesota for almost twenty-five years, retired January 1 as superintendent of Mineral Springs Sanatorium, Cannon Falls, a position he had held for the past seventeen years. A graduate of McGill University Faculty of Medicine, Montreal, Dr. Beadie practiced medicine in southern Minnesota and in St. Paul, became medical director of Pokegama Sanatorium in 1917 and of Mineral Springs in 1923. Dr. Karl H. Pfuetze, formerly of Nopeming, has been named to succeed Dr. Beadie at Mineral Springs.

NEW JERSEY

New York University Courses in Newark.—New York University College of Medicine is presenting a course in amputations at the City Hospital, Newark, Saturday mornings from March 1 to April 12. Dr. Henry H. Kessler, Newark, will be director of the course, which will be given for not less than six nor more than eighteen physicians. Applications should be sent to the Office of the Dean, New York University College of Medicine, 477 First Avenue, New York, before February 22. A course of lectures on diseases of the liver and biliary tract will be given at the Newark City Hospital under the direction of Dr. Manfred Kraemer Tuesday and Thursday mornings from February 25 through March 27. Applications for this course must be received by February 18. The class will be limited to twelve.

Society Ex-Presidents Back Aid to Britain.—All the living ex-presidents of the Medical Society of New Jersey issued a joint statement, January 22, pledging their support to the President of the United States in behalf of total defense and in his effort to give all material aid to Great Britain short of war, irrespective of cost. The statement further called on the representatives from New Jersey in Congress to lend their support to a program to give the fullest aid to Great Britain and her allies. It was signed by Drs. Edward J. Ill, Wells P. Eagleton, Francis R. Haussling and Edward M. Zeh Hawkes, Newark; Walt P. Conaway and William J. Carrington, Atlantic City; Lucius F. Donohue, Bayonne; Andrew F. McBride, Paterson; George N. J. Sommer, Trenton; Frederick J. Quigley, Union City; Lancelot Ely, Somerville; Marcus W. Newcomb, Browns Mills; Spencer T. Snedecor, Hackensack, and William G. Herrman, Asbury Park.

NEW YORK

Lectures for Practitioners.—The council committee on public health and education of the Medical Society of the State of New York arranged a "Teaching Day" for the Wyoming County Medical Society in Castile, January 8. The speakers were Drs. Francis J. Gustina, Buffalo, on "The Use of Biologicals in the Diagnosis and Treatment of Communicable Diseases, with Discussion of Technics and Results" and Ward L. Ekas, Rochester, on "The Hemorrhagic States of Pregnancy, Placenta Praevia and Other Conditions." Three lectures on pediatrics are being presented before the Chemung County Medical Society in Elmira. Dr. Charles Hendee Smith, New York, gave the first, January 8, on "Pneumonias of Childhood"; Dr. Katharine G. Dodge, New York, will speak February 12 on "Rheumatic Fever, Chorea and Heart Disease," and Dr. Gaylord W. Graves, New York, March 12 on "Preventive Pediatrics and the Periodic Health Examination."

Aviation Award Presented to Dr. Bauer.—The first John Jeffries Award in aviation medicine was presented to Dr. Louis H. Bauer, Hempstead, L. I., by the Institute of the Aeronautical Sciences in New York, January 28. John Jeffries was a physician, born in Boston in 1744, who graduated from Harvard and later practiced in London. In 1784 he made a flight from London with Blanchard, a French balloonist, during which he recorded temperature, humidity, electrical charges and density of the air. The next year Jeffries and Blanchard made the first crossing of the English Channel by air. The institute will present the award annually for contributions to the advancement of aeronautics through medical research. Dr. Bauer graduated from Harvard Medical School, Boston, in 1912 and entered the Medical Corps, U. S. Army, in 1913. He was the first commandant of the School of Aviation Medicine of the Army Air Corps; also the first medical director of the aeronautics branch of the U. S. Department of Commerce, serving from 1926 to 1930, in which year he resigned from the army. He organized and was the first president of the Aero Medical Association and is editor of the *Journal of Aviation Medicine* and consultant in aviation medicine and cardiology to the Civil Aeronautics Authority. He is attending cardiologist to the Nassau Hospital, Mineola, and to the Meadowbrook Hospital, Hempstead.

New York City

Fifth Harvey Lecture.—Howard B. Lewis, Ph.D., professor of biological chemistry and chairman of the department, University of Michigan Medical School, Ann Arbor, will deliver the fifth Harvey Lecture of the current series at the New York Academy of Medicine, February 20, on "The Significance of the Sulfur-Containing Amino Acids in Metabolism."

Symposium on Wheezing.—The Tuberculosis Sanatorium Conference of Metropolitan New York will hold a clinical session on chronic pulmonary disease February 19 at which a symposium on "Clinical Aspects of Wheezing" will be presented. The speakers will be Drs. Robert A. Cooke, from the standpoint of the allergist; Mervin C. Myerson, the bronchoscopist, and Paul Klempner, the pathologist.

Symposium on Vitamins.—Long Island College of Medicine, Brooklyn, presented a symposium at an all day meeting January 23 with the following speakers discussing avitaminosis in relation to the subjects given: Drs. Thomas T. Mackie, medicine and surgery; Arthur W. Grace, dermatology; Benjamin Kramer, Brooklyn, pediatrics; H. Russell Meyers, Brooklyn, nervous diseases; Alfred C. Beck, Brooklyn, obstetrics, and C. Raymond Wells, D.D.S., Brooklyn, oral conditions.

The Physician in National Defense.—The metropolitan New York chapter of the Association of Military Surgeons of the United States held a symposium on "The Mission of the Physician in National Defense," January 23, at the New York Academy of Medicine. The speakers were:

Dr. Claude C. Pierce, The Medical Officer in the U. S. Public Health Service.

Col. Howard W. Barker, The Medical Officer in the Veterans Administration.

Capt. Edward C. White, The Medical Officer in the U. S. Navy.

Col. Charles M. Watson, The Medical Officer in the U. S. Army.

Dr. Charles F. W. Bove, The Civilian Physician and National Defense.

Dr. Van Etten Honored.—The Bronx Medical Association gave a dinner December 7 in honor of Dr. Nathan B. Van Etten, President of the American Medical Association, celebrating his fiftieth year in the practice of medicine. More than one hundred and fifty attended. The group, of which Dr. Van Etten is a charter member, presented to him a watch inscribed "To Dr. Nathan B. Van Etten, President of the

American Medical Association, 1940; for fifty years zealous exponent of medical ideals and ethics, with high regard, from the Bronx Medical Association."

Lilly Award to Dr. Woolley.—Dilworth Wayne Woolley, Ph.D., fellow on the staff of the Rockefeller Institute for Medical Research, won the \$1,000 Lilly award and a bronze medal given at the annual convention of the Society of American Bacteriologists in St. Louis in December. The award, established by Eli Lilly and Company, is presented annually to a man or woman under 31 years of age who has made exceptional contributions to knowledge of bacteriology or immunology in a noncommercial or educational institution. Dr. Woolley was honored for his research on the hemolytic streptococcus. He graduated from the University of Alberta in 1935.

PENNSYLVANIA

Society News.—Dr. Thomas St. Clair, Latrobe, among others, addressed the Westmoreland County Medical Society, Greensburg, January 21, on "Analgesia in Obstetrics."—Dr. Jacques P. Guequierre, Philadelphia, addressed the Northampton County Medical Society, January 17, on "The General Practitioner and Everyday Dermatoses."—Dr. Frank H. Lahey, Boston, President-Elect of the American Medical Association, addressed the Lackawanna County Medical Society, Scranton, January 30, on "Surgery of the Stomach and Small Intestine."

Philadelphia

Program on Aviation Medicine.—The Philadelphia Laryngological Society had a program devoted to aviation medicine, February 4. The speakers were Comdr. John C. Adams, U. S. Navy, on "Aviation Medicine Today"; Comdr. John R. Poppen, U. S. Navy, "Otolaryngology and Physical Stresses in Modern Aviation"; Comdr. Travis S. Moring, U. S. Navy, "Aviation Ophthalmology"; Drs. Robert J. Hunter, "Experiences as a Flight Surgeon"; Alfred N. Richards, vice president for medical affairs, University of Pennsylvania, "General Considerations of Aviation Medicine," and Carl F. Schmidt, professor of pharmacology, University of Pennsylvania School of Medicine, "Recent Advances in Physiology Pertaining to Aviation Medicine."

VIRGINIA

Graduate Course in Specialties.—The seventh annual postgraduate course in ophthalmology and otolaryngology was held at the University of Virginia Department of Medicine, Charlottesville, December 10-13. The lecturers included Drs. Marvin F. Jones, New York; James Milton Robb, Detroit; Harry S. Gradle, Chicago; Frank B. Walsh, Baltimore, and Comdr. John R. Poppen, Bureau of Aeronautics, U. S. Navy.

Personal.—Dr. Bathurst B. Bagby, West Point, former director of the bureau of child health in the state health department, has been appointed city epidemiologist and chief health officer of Richmond on a temporary basis. Dr. William A. Browne resigned as epidemiologist and acting health officer to become health officer of Alexandria. The position of health officer had not been filled since the advent of a new city administration. Dr. Bagby retired from the state service in July 1940.—Dr. George A. Welchons, assistant director of Pine Camp Hospital, Brook Hill, city tuberculosis hospital for Richmond, has been appointed superintendent and medical director to succeed Dr. Percy E. Schools, resigned.

WASHINGTON

Surgical Meeting.—Dr. Allen O. Whipple, New York, was the guest speaker at the annual meeting of the Seattle Surgical Society at the King County Hospital, Seattle, January 31 and February 1. Dr. Whipple discussed the papers presented by local surgeons each morning and afternoon and made addresses at two dinner meetings on "Surgery of the Pancreas" and "Results of Decompression with Intestinal Intubation in Surgery of the Intestinal Tract."

Society News.—Drs. Rudolph G. Andres and George H. Anderson addressed the Spokane County Medical Society, Spokane, January 9, on "Intestinal Obstruction" and "Hyperventilation Syndrome" respectively.—Dr. Caspar W. Sharples, Seattle, addressed the Grays Harbor County Medical Society at its December meeting on "Differential Diagnosis of Abdominal Conditions."—Karl F. Meyer, Ph.D., San Francisco, addressed the Walla Walla Valley Medical Society, Walla Walla, January 16, on "Virus Diseases."—Dr. Frederick A. Slyfield, Seattle, addressed the Pierce County Medical Society, Tacoma, January 14, on "Diseases of the Chest."

GENERAL

Congress on Dental Education.—The Council on Dental Education of the American Dental Association will hold a Congress on Dental Education and Licensure at the Stevens Hotel, Chicago, February 15. The speakers will include:

Dr. Ray Lyman Wilbur, Stanford University, Calif., chairman of the Council on Medical Education and Hospitals of the American Medical Association, Professional Education and Licensure.
Dr. Charles Sidney Burwell, dean, Harvard Medical School, Boston, The Harvard Plan of Dental Education.
John T. O'Rourke, D.D.S., dean, University of Louisville School of Dentistry, The Aims of Dental Education.
Harold W. Alden, D.D.S., Northampton, Mass., chairman, National Board of Dental Examiners, The Functions and Methods of the National Board of Dental Examiners.
Morton H. Jones, D.D.S., secretary, Ohio State Dental Board, Columbus, The Aims of Licensure in Dentistry.
Edward S. Jones, Ph.D., professor of psychology, University of Buffalo, The Philosophy and Procedure of the Examining Process.
J. Ben Robinson, D.D.S., dean, Baltimore College of Dental Surgery of the University of Maryland, Functions of the Council on Dental Education.

Mid-South Post Graduate Assembly.—The fifty-sixth annual session of the Mid-South Post Graduate Assembly will be held in Memphis, Tenn., February 11-14 at the Hotel Peabody. The guest speakers will include:

Major Gen. James C. Magee, Washington, D. C., Medical Preparation for the Present Emergency.
Dr. Henry P. Wagener, Rochester, Minn., Diagnostic and Prognostic Significance of Retinal Glomerulonephritis.
Dr. Eldridge L. Eliason, Philadelphia, Surgical Aspects of Gastrointestinal Hemorrhage.
Dr. William D. Stroud, Philadelphia, Digitalis, Its Indications and Best Method of Administration.
Dr. Elmer L. Sevringhaus, Madison, Wis., Obesity, Types and Treatment.
Dr. Bret Ratner, New York, The Asthmatic Child.
Dr. Dallas B. Phemister, Chicago, Conservative Surgery in the Treatment of Sarcoma.
Dr. Marion A. Blankenhorn, Cincinnati, Nutritional Disorders of the Nervous System.
Dr. Leon Herman, Philadelphia, The Physiological and Clinical Significance of Renal Symptoms.
Dr. Verne C. Hunt, Los Angeles, Surgical Considerations of Obstructive Jaundice.

Dr. James L. Dunavant, Ripley, Tenn., is president of the assembly and Dr. Clyde M. Speck, New Albany, Miss., is president-elect.

Conference on Medical Service.—The fifteenth annual meeting of the National Conference on Medical Service, formerly the Northwest Regional Conference, will be held in the Red Lacquer Room, Palmer House, Chicago, Sunday, February 16. Dr. Forrest L. Loveland, Topeka, is president, and Dr. Harold M. Camp, Monmouth, Ill., secretary. The first session will be devoted to discussion of voluntary group medical programs with the following speakers: Mr. J. D. Laux, executive director, Michigan Medical Service, Detroit; Dr. William M. Hartman, Macomb, and Mr. J. George Crownhart, Madison, Wis. Medical preparedness will be discussed by Drs. Irvin Abell, Louisville; Morris Fishbein, Chicago, Editor of THE JOURNAL; Leonard G. Rowntree, chief, medical division, selective service system, Washington, D. C., and Olin West, Chicago, Secretary and General Manager of the American Medical Association. State medical societies' postgraduate programs will be discussed by Drs. Howard E. Snyder, Winfield, Kan., William A. O'Brien, Minneapolis, and Robert S. Berghoff, Chicago. Federal and state legislative problems will be presented, respectively, by Dr. Edward H. Cary, Dallas, and Mr. J. W. Holloway Jr., Chicago. Medical care for social security clients will be considered by Mr. Walter F. Fink, director, Minnesota Division of Social Welfare, department of social security, St. Paul; Dr. Alfred W. Adson, Rochester, Minn.; Mr. Walter G. Stumbo, Topeka, Kan., and Dr. Charles H. Phifer, Chicago. Mr. C. H. Wantz, president, Medical Exhibitors Association, Chicago, will discuss "The Annual Meetings from the Standpoint of the Exhibitor."

CORRECTION

"Vitamin Sweets."—In the editorial on this subject which appeared in THE JOURNAL for January 18, a footnote stated that the vitamin A concentrate used was probably that of the Eastman Kodak Company. We are informed that the Distillation Products, Inc., of Rochester, N. Y., took over the patents and work on this subject from the Eastman Kodak Company in June 1939. This company sells vitamin A concentrate in bulk to food and drug manufacturers. None is sold retail. The company states that it has supplied limited quantities of these concentrates to Dr. Newton, but the company has made no recommendation nor has it been active in any way in promoting "Vitamin Sweets."

Foreign Letters

LONDON

(From Our Regular Correspondent)

Dec. 14, 1940.

Temporary Registration for United States and Canadian Physicians

A defense regulation has been passed which enables physicians legally entitled to practice in any territory outside the United Kingdom to which the regulation is applied to be temporarily registered in the Colonial or Foreign Section of the Medical Register for a period not longer than that of the present emergency, if it is shown to the satisfaction of the General Council of Medical Education and Registration that the physicians fulfil the prescribed conditions. An order has been made by the council applying the regulation to each of the provinces of Canada and to the United States. The order prescribes as conditions of temporary registration that applicants shall be (1) British subjects or citizens of the United States, (2) shall be of good character and (3) shall hold a medical diploma granted in a province of Canada or in the United States which is recognized for the time being by the council for the purposes of the order as furnishing sufficient guaranty of the possession of the requisite professional knowledge and skill. The way is thus opened to our colleagues in Canada and the United States who wish to give practical expression to their belief that our cause is their cause by placing their services at the disposal of the British government as long as the emergency lasts.

End of Medical Reciprocity with Italy

At the same time as the Council announced this order it put an end to the order made forty years ago establishing medical reciprocity with Italy. The president stated that for the greater part of this long period Italy had taken privileges far more extensive than any that she gave. The right of persons already entered on the foreign list of the Medical Register by virtue of diplomas granted in Italy is not prejudiced by the new position.

War Economy in Dermatologic Prescribing

In a previous letter the disuse of drugs which have to be imported and the substitution for them of equivalents produced at home, in order to conserve cargo space for war purposes, was described. The special field of dermatologic prescribing has been dealt with by the Therapeutics Requirements Committee of the Medical Research Council in a memorandum of suggestions. It is pointed out that, for many of the purposes for which ointments are prescribed, pastes and creams are more satisfactory and they require only about half the amount of fatty basis. Fatty vehicles can sometimes be replaced by wet dressings (with or without mucilage), antiseptic paints and varnishes or powders. With regard to antiseptics, boric acid and iodine need not be used in dermatology. The amount of mercury used can be greatly reduced by limiting it to cases in which other antiseptics have not proved satisfactory. If the antiseptics were limited to aniline dyes, coal tar derivatives, salicylic acid, sulfur, ichthammol, resorcinol, dioxanthranol, silver nitrate and tar, the treatment of most cutaneous diseases would not suffer much. For the treatment of ringworm, mercurials and iodine are rarely required, whereas a paste containing fuchsin and Whitfield's ointment of benzoic and salicylic acid are effective and freely available. If epidemics of scabies should occur, treatment will be most economical by dermatologists. Sulfur ointment still remains one of the most efficacious remedies. If benzyl benzoate is scarce, it had best be reserved for the treatment of children.

For the treatment of pediculosis of the body or scalp, oily dressings are not essential, though of some value in pediculosis pubis.

The committee has divided dermatologic drugs into the same groups as in the previous memorandum: 1. Those readily available or essential—acriflavine, aniline dyes, benzoic acid, calamine, chloroform, coal tar, ether, hydrochloric acid, hydrogen peroxide, ichthammol, kaolin, saponated solution of cresol, phenol, resorcinol, salicylic acid, silver nitrate, sodium bicarbonate, sulfur, tannic acid, wool fat and zinc. 2. Drugs essential for certain purposes, to which they should be restricted. In the following list substitutes are given in parentheses: aluminum acetate (lead acetate), boric fomentations (saline compresses), chrysarobin (dioxanthranol), iodine (proflavine, acriflavine, trinitrophenol, crystal violet or brilliant green), magnesium sulfate (sodium sulfate). 3. Drugs whose efficacy does not justify importation or manufacture in wartime—almond oil and sulfurated potash. For the latter, sulfur ointment or sulfurated lime could be substituted.

American Red Cross Aids British Children

By far the largest help from America to Britain, apart from military supplies, has been in the form of gifts from the American Red Cross, which amount to \$12,500,000. Besides cash contributions the American Red Cross, which is organized in three thousand, seven hundred chapters covering the forty-eight states, has "Aid-to-Britain" groups making clothing of all kinds to help our war effort. Already thirty-five large country houses have been taken over as nursery homes for bombed London children. The cost of their maintenance is being borne by the junior branch of the American Red Cross—that is, by the children of America, who will also provide thirty thousand Christmas boxes for children bombed out of their houses and living in the shelters of London and other cities. Mr. Daniel Grant, chairman of the American Red Cross Committee in Great Britain, has declared that "the American people, through the American Red Cross, have made a great effort to help the people of Britain. It is an effort second only in importance to the supplies of munitions and aircraft reaching here from America."

The American Red Cross distributes its supplies through the British Red Cross and the Women's Voluntary Services. Some idea of the amount of help given is shown by a recent inventory of Mr. Grant, which reveals the promise of one hundred and thirty-six fully equipped mobile canteens, twenty of which are already in operation, twelve of which are working in London and take food every night to auxiliary fire service men, air raid wardens, police and first line shelters. Other gifts include one hundred and twenty thousand pairs of boots and shoes and a million garments for air raid victims. A quarter of a million yards of material has been purchased in Great Britain for the Women's Voluntary Service, who will work it up into garments. The British Red Cross has also received one hundred and ten ambulances and is promised another three hundred in the near future, ten complete roentgen ray units, thirteen fully equipped operating tables, large quantities of blood plasma given by people in America, all kinds of medical supplies, hospital equipment and clothing.

Leiden University in the Netherlands Is Closed

News has been received in London of the closure by the Germans of the famous university of Leiden. The reason given is that the students have been "obstructive," which in ordinary language means that the pursuit of truth in accordance with the tradition upheld by Leiden for more than three and one-half centuries is inconsistent with nazi doctrines. It may be recalled that Boerhaave, one of the fathers of modern medicine, taught at Leiden and attracted vast audiences from all over Europe. Edinburgh's great medical school can be

traced to Boerhaave's lecture room. In Leiden's early days Scaliger added to its glory and in the present day Einstein has done so. The physicist Lorentz was proud of his Leiden professorship, and there at the beginning of this century Omnes carried out his famous experiments on gases at extremely low temperatures, culminating in his liquefaction of helium. Truly Europe is witnessing an eclipse of her higher civilization.

Masks in the Prevention of Infection

A committee of the House of Commons has recommended the wearing of a simple form of mask in air raid shelters during epidemics, with the object of preventing infection. During the fatal epidemic of influenza which followed the last great war, masks were worn in some hospitals by all who entered the wards. Though the infection was most virulent, physicians, nurses and attendants escaped with few exceptions. The masks consisted only of a pad of white gauze secured by tapes. As the season of influenza epidemics is near, it has been suggested that the dislocation of industry caused every year by this disease could be reduced to a minimum and the millions of working hours—so important just now—could be saved if masks were introduced into factories and workshops as well as into air raid shelters.

The Prevention of Diphtheria

In reply to a question in the House of Commons by Prof. A. V. Hill (the physiologist), the minister of health stated that the annual number of cases of diphtheria in England and Wales is about 60,000, of which 54,000 occur in children under the age of 15. The average number of children under 15 who die from diphtheria is 2,700. The average number of hospital beds occupied by diphtheria patients is five thousand, and the annual cost of the hospital treatment is \$5,000,000. The minister stated that experience in Canada and the United States showed that the disease can be almost entirely eliminated by the immunization of children. In view of the fact that children are now being freely moved from one area to another (in the evacuation due to air raids), Professor Hill asked whether the necessary agents for preventive inoculation might not now be provided as a national charge instead of one on the local authorities. Also in view of concern as to the spread of infection in crowded air raid shelters would the Ministry of Health take more active steps to protect the child population against diphtheria. The minister replied that his policy was to encourage local authorities to provide facilities for immunization and to do their best to persuade parents to take advantage of them. The cost of the necessary material in the present war conditions would be reimbursed to the local authorities by the government.

Sir Henry Dale President of the Royal Society

The highest scientific honor in this country, the presidency of the Royal Society, has been conferred on Sir Henry Dale in succession to Sir William Bragg. Since 1663 there have been forty-four presidents of the Royal Society, and Dale is the eighth member of the medical profession to hold the office. He has never engaged in practice as a physician but has devoted himself to research. His medical education took place at St. Bartholomew's Hospital and University College. From 1904 to 1914 he was director of the Wellcome Physiological Research Laboratories. He then was appointed head of the department of biochemistry and pharmacology of the Medical Research Council. In 1928 he was made director of the National Institute of Medical Research, which he still is.

His first step in the researches which have made him famous was his investigation of the action of acetylcholine in 1914, but not till 1929 was he able, in collaboration with Dudley, to isolate it from an animal organ in quantities sufficient to be identified chemically. Observations on the frog's heart by Loewi and further researches by Dale, with other collabora-

tors, led to the knowledge that acetylcholine is the substance liberated at parasympathetic endings and the endings of preganglionic fibers in autonomic ganglions. It was later shown that it is liberated also at the endings of voluntary motor nerves. Dale introduced the terms "cholinergic" and "adrenergic" to describe action of the nerve fibers of the autonomic system in terms of chemical function. Another research of fundamental importance, in collaboration with Berger and Laidlaw, was on the active principles of ergot, which led to the identification of the alkaloid ergonovine. From his work on ergot developed his researches on the action of histamine and its analogy with surgical shock, which were carried out during the last war. His training and direction of workers in the field of biochemistry have been of far reaching importance. In 1919 he delivered the Herter lecture at the Johns Hopkins University. In 1936 he shared the Nobel prize for medicine.

Marriages

ALBERT JOSEPH ORLOSKY, Arlington, Va., to Miss Nancy Elise Conley of Washington, D. C., in October 1940.

GEORGE RUDOLPH LAUB, New Bern, N. C., to Miss Harriet Elizabeth Stith of Columbia, S. C., in October 1940.

PAUL L. SINGER, Des Moines, Iowa, to Miss Shirley E. Ellis of Hillsdale, Mich., in Chicago, Oct. 26, 1940.

HOMER JACKSON HANCOCK, Welch, W. Va., to Miss Harriet Loyd Hudgins of Warrenton, N. C., Oct. 26, 1940.

KENDALL O. KENNEDY, Columbus, Ohio, to Miss Laura K. Campbell in Paw Paw, Mich., in October 1940.

FRANK MATTHEWS PARISH, Brunswick, Ga., to Miss Martha Elizabeth Mobley of Atlanta in October 1940.

WILLIAM EDWARD ADAIR JR. to Miss Lucy Blake Ward, both of Wilmington, N. C., in October 1940.

JAMES MONTELEONE CIARAVELLA, New Orleans, to Miss Frances Anzalone at Independence recently.

DANIEL SMITH CURRIE JR., Parkton, N. C., to Miss Marion Cox Wood near Vanceboro, Oct. 26, 1940.

ANDREW M. JAMISON JR., Spartanburg, S. C., to Miss Evelyn Byrd Hardin in Cincinnati, Oct. 27, 1940.

WILLIAM LOVELL WRIGHT, West Liberty, Ky., to Miss Eva Sara Murphy of Lexington, Oct. 12, 1940.

DUDLEY Y. OLDHAM, Houston, Texas, to Miss Cornelia Cobb of Longville, La., Oct. 20, 1940.

HOYT R. ALLEN to Mrs. Martha Branham, both of Little Rock, Ark., at Benton, Oct. 19, 1940.

GENE L. TEPLY to Miss Agnes Josephine Eustcrbrock, both of Howells, Neb., Oct. 26, 1940.

JOHN M. COOK, Pittsburgh, to Miss Velma Elizabeth Bowser of Beaver Falls, Pa., in October 1940.

BASSEL NELSON BLANTON, Temple, Texas, to Miss Frances Carol Crain of Waco, Oct. 30, 1940.

ARTHUR PARK MCGINTY, Atlanta, Ga., to Miss Murray Smith of Birmingham, Ala., recently.

PAUL E. DINGLE, New Castle, Ind., to Miss Marian Atchison of East Palestine, Ohio, recently.

LELAND B. GOULD, Coquille, Ore., to Miss Mabel E. Henderson of Portland in October 1940.

JOHN GRAHAM NORRIS, Farmerville, La., to Miss Mary Incz Taylor in Monroe in October 1940.

ALAN STANFORD HORWITZ, New York, to Miss Charlotte Vangrov of Dayton, Ohio, recently.

JOHN E. ALLGOOD JR. to Miss Virginia Marie Schiller, both of Petersburg, Ohio, Oct. 21, 1940.

CHARLES CRAIG GASS, Kearney, Neb., to Miss Doris Edna Griffiths of Omaha, Oct. 19, 1940.

CLARENCE F. KELLY JR., Duquoin, Ill., to Miss Lillian Masters of Butler in October 1940.

WILLIAM MCCONNELL JONES, Gastonia, N. C., to Miss Elizabeth Garlington, Oct. 14, 1940.

LEWIS HOWARD McDONALD to Miss Lois Reeves, both of Atlanta, Ga., Oct. 12, 1940.

Deaths

Carl Roger Darnall ♂ Brigadier General, United States Army, retired, Washington, D. C., died, January 18, in the Walter Reed General Hospital of arteriosclerosis, aged 73. General Darnall was born Dec. 25, 1867 in Weston, Texas; he graduated from the Jefferson Medical College of Philadelphia in 1890 and the Army Medical School in 1897. He entered the military service Oct. 27, 1896 and was appointed captain and assistant surgeon Oct. 26, 1901, major April 23, 1908, lieutenant colonel July 1, 1916 and colonel May 15, 1917. His first service was with the 23d infantry at Fort Clark, Texas. In 1900 he was on duty at the United States Military Hospital in Havana, Cuba. From May 1900 to April 1901 he served as operating surgeon and pathologist on the hospital ship *Relief*. He commanded the Military Hospital at Iloilo, Philippine Islands, 1901-1902; in June 1902 he returned to the United States and was on duty in the Office of the Surgeon General, Washington, D. C. From June 1903 until 1913 he was on duty at the Army Medical School, serving as adjutant and secretary of the faculty, instructor in sanitary chemistry and operative surgery. During that period he was in charge of the medical supply depot, Washington, D. C., a member of the army examining board and of the joint board of army and navy medical officers. Brigadier General Darnall served in the Philippine Islands from April 1914 until July 1916 at the Department Hospital in Manila and at the Medical Supply Depot. Returning to the United States in August 1916, he again served in the Office of the Surgeon General as executive officer. In December 1922 he was transferred to Hawaii, where he served as department surgeon. In August 1925 he was ordered to duty in the Office of the Surgeon General, where he served as executive officer until 1929, when he was appointed assistant surgeon general with rank of brigadier general, commanding the Army Medical Center. Brigadier General Darnall was awarded the Distinguished Service Medal. He retired Dec. 31, 1931 by operation of law. He was a fellow of the American College of Surgeons. In 1910 he originated the liquid chlorination of water for the safeguarding of water supplies.

Paul Ferdinand Schilder ♂ New York; Medizinische Fakultät der Universität Wien, Austria, 1909; research professor of psychiatry at the New York University College of Medicine; member of the American Neurological Association, American Psychiatric Association and the American Psychopathological Association; clinical director of the psychiatric division of Bellevue Hospital; served in the Austrian Army during the World War; author of "Introduction to a Psycho-analytic Psychiatry" and several books published in Berlin and Vienna; aged 54; died, Dec. 8, 1940, in the Misericordia Hospital of injuries received when he was struck by an automobile.

Louis Casper Duncan ♂ Colonel, United States Army, retired, St. Petersburg, Fla.; Kansas Medical College, Topeka, 1896; demonstrator and assistant professor of anatomy at his alma mater from 1896 to 1898; veteran of the Spanish-American War; entered the medical corps of the Army as a first lieutenant on Oct. 27, 1902 and graduated the following year from the Army Medical School; reached the grade of lieutenant colonel on May 15, 1917 and was retired on March 2, 1920; during the World War was given the temporary grade of colonel and was advanced to that grade on the retired list on June 21, 1930; aged 71; died, Oct. 19, 1940, of bronchopneumonia.

William S. Smith, Baltimore; University of Maryland School of Medicine, Baltimore, 1883; clinical professor of gynecology at his alma mater, now the University of Maryland School of Medicine and College of Physicians and Surgeons; professor of gynecology at the Maryland Medical College from 1898 to 1913; surgeon, city police department from 1888 to 1898; examiner, state board of labor and statistics from 1916 to 1919; aged 80; for many years consultant in gynecology at the E. C. Hazard Hospital, Long Branch, N. J., and on the staff of the Franklin Square Hospital, where he died, Dec. 9, 1940, of uremia due to carcinoma of the prostate.

Clelia Duel Mosher, Stanford University, Calif.; Johns Hopkins University School of Medicine, Baltimore, 1900; assistant professor of personal hygiene, Stanford University, from 1910 to 1922, associate professor from 1922 to 1928, professor, 1928-1929 and professor emeritus since 1929, and medical adviser of women from 1910 to 1929; medical investigator, children's bureau, and assistant medical adviser and later associate medical director, Bureau of Refugees and Relief, American Red Cross in France, from 1917 to 1919; aged 77; died, Dec. 22, 1940.

Karl Sigismund Blackwell ♂ Richmond, Va.; University College of Medicine, Richmond, 1906; professor of otolaryngology, Medical College of Virginia; fellow of the American College of Surgeons; past president and vice president of the Virginia Society of Ophthalmology and Otolaryngology; formerly vice president of the Medical Society of Virginia; past president of the Richmond Academy of Medicine; on the staff of the Hospital Division of the Medical College of Virginia; aged 61; died, Dec. 26, 1940, of coronary thrombosis.

Robert Pelton Wadhams ♂ New York; University and Bellevue Hospital Medical College, New York, 1906; professor of clinical surgery at his alma mater, now known as the New York University College of Medicine; fellow of the American College of Surgeons; served during the World War; attending surgeon, Bellevue Hospital; associate attending surgeon, French Hospital; consulting surgeon, Charlotte Hungerford Memorial Hospital, Torrington, Conn.; aged 61; died, Dec. 16, 1940, of heart disease.

de Wayne Greenwood Richey ♂ Pittsburgh; University of Pittsburgh School of Medicine, 1915; assistant professor of laryngology and rhinology at his alma mater; member of the American Association of Pathologists and Bacteriologists; fellow of the American College of Surgeons; served during the World War; aged 48; on the staffs of the Mercy Hospital, Pittsburgh, and the Columbia Hospital, Wilkensburg, Pa., where he died, Dec. 5, 1940, of portal cirrhosis of the liver.

John Templeton Bowen, Boston; Harvard Medical School, Boston, 1884; member of the Massachusetts Medical Society; instructor of dermatology at his alma mater from 1896 to 1912, assistant professor from 1902 to 1907, Edward Wigglesworth professor from 1907 to 1912 and since 1912 professor emeritus at his alma mater; for many years on the staff of the Massachusetts General Hospital; aged 83; died, Dec. 3, 1940, of pyelonephritis.

Percy Hypes Swahlen ♂ St. Louis; St. Louis University School of Medicine, 1903; associate professor of gynecology and obstetrics at his alma mater; fellow of the American College of Surgeons; past president of St. Louis Medical Society; obstetrician, St. Ann's Maternity and Mount St. Rose hospitals; visiting obstetrician and gynecologist, St. Louis City Hospital; gynecologist, St. John's Hospital; aged 63; died, Dec. 10, 1940, of coronary thrombosis.

Louis Emmitt Brown ♂ Akron, Ohio; Baltimore Medical College, 1903; member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological Association; fellow of the American College of Surgeons; member of the city board of health; served during the World War; past president of the Akron Academy of Ophthalmology and Otolaryngology; on the staff of the City Hospital; aged 59; died, Dec. 11, 1940.

Ogden Matthias Edwards Jr. ♂ Pittsburgh; Columbia University College of Physicians and Surgeons, New York, 1896; professor of pediatrics at the University of Pittsburgh School of Medicine from 1909 to 1919 and acting dean from 1917 to 1919; formerly a member of the staffs of the Western Pennsylvania Hospital, St. Francis Hospital and the Children's Hospital; aged 71; died, Dec. 28, 1940.

Arthur Elias Leitch ♂ Saginaw, Mich.; Detroit College of Medicine, 1893; past president and secretary of the Saginaw County Medical Society; served during the World War; aged 68; on the staffs of Saginaw General Hospital, St. Luke's Hospital and St. Mary's Hospital, where he died, Dec. 9, 1940, of abscess of the right kidney.

Walter Scott Turnbull, Vancouver, B. C., Canada; University of Toronto Faculty of Medicine, 1903; member of the North Pacific Surgical Association; past president of the British Columbia Medical Association; for many years on the staff of the Vancouver General Hospital and the Grace Hospital; aged 62; died in November 1940.

Edward Leo Zimmerman ♂ Eugene, Ore.; Jefferson Medical College of Philadelphia, 1912; served during the World War; past president of the Oregon State Medical Society and the Lane County Medical Society; on the staff of the Sacred Heart Hospital; aged 51; died, Dec. 2, 1940, of arteriosclerosis, thrombosis and myocarditis.

Joseph Sylvester Miller, York, Pa.; College of Physicians and Surgeons, Baltimore, 1880; member of the Medical Society of the State of Pennsylvania; past president of the York County Medical Society; served on the staff of the York Hospital in various capacities; aged 84; died, Dec. 8, 1940, of thrombosis and gangrene.

George D. Lummis, Middletown, Ohio; Medical College of Ohio, Cincinnati, 1884; president of the International Health Officers Association; for more than half a century health commissioner of Middletown; for many years member of the Ohio Public Health Council; aged 77; died, Dec. 26, 1940, of coronary thrombosis.

Charles F. Zeller ☉ Jerome, Idaho; University Medical College of Kansas City, Mo., 1903; past president of the Southside Medical Society; on the staff of St. Valentine's Hospital, Wendall; aged 60; died, Dec. 1, 1940, in Rochester, Minn., of carcinoma of the colon and peritonitis.

Arthur Raphael Brennan, Brooklyn; Baylor University College of Medicine, Dallas, Texas, 1921; member of the Medical Society of the State of New York; on the staffs of St. Peter's Hospital and St. Mary's Hospital; aged 44; died, Dec. 11, 1940, of coronary thrombosis.

Clarence Ross Hepler ☉ Parsons, Kan.; University Medical College of Kansas City, Mo., 1902; member of the American Psychiatric Association; at one time health officer of Cherokee County and Sedgwick County; aged 66; died, Nov. 17, 1940, of coronary thrombosis.

A. J. Markley, Belvidere, Ill.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1881; member and for many years treasurer of the Illinois State Medical Society; aged 82; died, Dec. 13, 1940, in St. Joseph's Hospital of carcinoma of the transverse colon.

William Langdon Haskell ☉ Lewiston, Maine; Medical School of Maine, Portland, 1894; fellow of the American College of Surgeons; served during the World War; on the staff of St. Mary's General Hospital; aged 70; died, Dec. 9, 1940, of arteriosclerosis.

Edward William Bing, Chester, Pa.; Jefferson Medical College of Philadelphia, 1877; member of the Medical Society of the State of Pennsylvania; also a pharmacist; aged 84; formerly on the staff of the Chester Hospital, where he died, Dec. 10, 1940.

Henry Augustus Kurth ☉ Schenectady, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1890; for many years on the staff of the Ellis Hospital; aged 77; died, Dec. 7, 1940, of carcinoma of the prostate.

J. Sumner Teter, Toledo, Ohio; Starling Medical College, Columbus, 1904; member of the Ohio State Medical Association; for many years on the staff of the Robinwood Hospital; served during the World War; aged 63; died, Dec. 6, of cerebral hemorrhage.

William George Carnathan ☉ Butler, Ala.; Medical College of Alabama, Mobile, 1905; president of the Choctaw County Medical Society; formerly county health officer; aged 58; died, Nov. 30, 1940, in Riley's Hospital, Meridian, of intestinal obstruction.

Herman Verplanck Hoffman ☉ San Francisco; University of California Medical Department, San Francisco, 1905; served during the World War; on the staffs of St. Mary's Hospital and Dante Hospital; aged 58; died, Nov. 16, 1940, of coronary disease.

Thomas Francis Maher ☉ Newington, Conn.; Yale University School of Medicine, New Haven, 1901; served during the World War; on the staff of the Veterans Administration Facility; aged 62; died, Dec. 18, 1940, of chronic myocarditis.

Jacob Kinzer Shell, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1881; aged 78; died, Dec. 10, 1940, in the Presbyterian Hospital of hypertrophy of the prostate and arteriosclerotic heart disease.

Norman Clyde Mills, Clarion, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; aged 63; died, Dec. 6, 1940, in the Brookville (Pa.) Hospital of injuries received when he was struck by an automobile.

Carlo D. Martinetti ☉ Orange, N. J.; Regia Università degli Studi di Siena Facoltà di Medicina e Chirurgia, Italy, 1903; on the staff of the Community Hospital, Montclair; aged 62; died, Dec. 9, 1940, of cerebral hemorrhage.

Arthur Rockwell Addy, Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1899; served during the World War; aged 70; died, Dec. 13, 1940, in the Kings County Hospital of arteriosclerosis.

George Walley Heck, Bethlehem, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1907; member of the Medical Society of the State of Pennsylvania; aged 59; died, Dec. 9, 1940, of cerebral hemorrhage.

Greene L. Johnson ☉ Harrodsburg, Ky.; Hospital College of Medicine, Louisville, 1907; past president of the Mercer County Medical Society; formerly county health officer; aged 56; died, Dec. 4, 1940, of carcinoma.

Charles M. Seaton, Morrisonville, Ill.; Illinois Medical College, Chicago, 1902; member of the Illinois State Medical Society; aged 64; died, Dec. 4, 1940, in St. Vincent Hospital, Taylorville, of angina pectoris.

L. Lester Self, Cherryville, N. C.; University College of Medicine, Richmond, 1901; aged 62; died, Dec. 4, 1940, in the Charlotte (N. C.) Eye, Ear and Throat Hospital of myocarditis and coronary thrombosis.

Ned Snyder, Brownwood, Texas; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1909; member of the State Medical Association of Texas; aged 55; died in November 1940.

William Edward McGuire, Cottonwood, Ill.; Barnes Medical College, St. Louis, 1899; member of the Illinois State Medical Society; for many years county coroner; aged 67; died, Dec. 10, 1940, of heart disease.

Robert Lewis Segrest, Wisner, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1907; member of the Louisiana State Medical Society; aged 58; died, Nov. 29, 1940.

Tilton Edwin Tillman ☉ San Francisco; Cooper Medical College, San Francisco, 1902; served during the World War; aged 59; died, Dec. 5, 1940, of coronary occlusion and pulmonary infarction.

Samuel Miles Robinson, Orlando, Fla.; Hahnemann Medical College and Hospital of Philadelphia, 1912; aged 84; died, Dec. 4, 1940, of typhus fever, chronic myocarditis and arteriosclerosis.

Nathan David Garnsey ☉ Kinderhook, N. Y.; Albany (N. Y.) Medical College, 1891; served during the World War; aged 76; died, Dec. 4, 1940, of cerebral thrombosis and arteriosclerosis.

Amos Carson Duncan, Forest City, N. C.; North Carolina Medical College, Charlotte, 1919; aged 46; died, Dec. 10, 1940, in Hollandale, Fla., of mesenteric thrombosis and cirrhosis of the liver.

John Joseph Kowarskas, Chicago; Chicago Medical School, 1927; member of the Illinois State Medical Society; aged 42; died, Dec. 14, 1940, in the Holy Cross Hospital of diverticulitis.

Frank R. Shoemaker, Hollidaysburg, Pa.; Medico-Chirurgical College of Philadelphia, 1895; aged 66; died, Dec. 2, 1940, in the Nason Hospital, Roaring Spring, of septicemia.

James Thruston Wolfe ☉ Washington, D. C.; George Washington University School of Medicine, Washington, 1908; aged 59; died, Dec. 8, 1940, of coronary occlusion.

James Pringle Crawford, Nashville, Tenn.; University of Maryland School of Medicine, Baltimore, 1893; served during the World War; aged 73; died, Nov. 25, 1940.

Joseph S. Lehman, Midway, Ky.; Cleveland Medical College, 1896; aged 71; died, Dec. 13, 1940, in the Good Samaritan Hospital, Lexington, of ruptured aneurysm.

Lee A. Wixsom ☉ Chicago; Chicago Medical School, 1918; aged 48; died, Dec. 9, 1940, in the Englewood Hospital of septicemia, pyemia and diabetes mellitus.

William Edmund Aughinbaugh, New York; National University Medical Department, Washington, D. C., 1897; also a lawyer; aged 69; died, Dec. 18, 1940.

James Balance Wood, St. Louis; St. Louis College of Physicians and Surgeons, 1917; served during the World War; aged 47; was found dead, Nov. 23, 1940.

Albert Sidney Steagall, Abbeville, Ala.; Medical College of Alabama, Mobile, 1888; formerly bank president; aged 74; died, Nov. 28, 1940, of heart disease.

Benjamin Lucas Norwood, McBee, S. C.; Louisville (Ky.) Medical College, 1887; aged 74; died, Dec. 8, 1940, of bronchopneumonia and nephritis.

Thomas C. Williams, New York; New York Homeopathic Medical College, New York, 1881; aged 82; died, Dec. 5, 1940, of myeloid leukemia.

William Fraser Mackay, Port Washington, B. C., Canada; University of Toronto Faculty of Medicine, 1900; aged 70; died in November 1940.

Lytle Caldwell Adams, La Grange, N. C.; North Carolina Medical College, Davidson, 1903; aged 63; died, Dec. 8, 1940, of heart disease.

ACUTE APPENDICITIS IN MILITARY HOSPITALS

To the Editor:—An extensive experience in the management of acute appendicitis during the World War led to the publication of an article entitled "Immediate Surgical Management of Acute Appendicitis in Military Hospitals" (*Surg., Gynec. & Obst.* 28:303 [March] 1919), suggesting a possible relationship between the onset of this condition in those cases in which there is a history of previous attacks and the method of administering the triple typhoid vaccine.

In view of the fact that a new army is being inducted into service, it seems to me that this article carries some conclusions that may be of importance, especially to the younger medical officers of the army. I would therefore call special attention to the lowering of the white blood cell count following the administration of triple typhoid vaccine, with a lower white cell count at the onset of an attack of acute appendicitis.

The blood picture sometimes puzzled medical officers in making a prompt diagnosis of acute appendicitis. Any factor which may delay a decision in making a prompt diagnosis in acute appendicitis is hazardous and must be corrected in order that surgery may not be delayed. I shall not attempt to discuss the relative importance of examinations of the blood as one of the factors in making a prompt diagnosis in acute appendicitis; suffice it to say that it may be of paramount importance in certain diagnostic decisions in acute abdominal conditions.

HUGH McKENNA, M.D., Chicago.

ROLE OF LACTIC ACID IN DENTAL CARIES

To the Editor:—In THE JOURNAL of January 4 there is a communication from Dr. J. Lewis Blass, who in Correspondence discusses the studies of Neuwirth and Klosterman on the production of lactic acid by oral micro-organisms after the introduction of concentrated carbohydrate into the mouth. Dr. Blass states: "Control experiments by these workers demonstrate that this rapid production of lactic acid in the oral cavity can be ascribed to the activity of oral micro-organisms. Thus, for the first time now there is not only a demonstration of the production of acids in the oral cavity but also a demonstration of the production of a definite acid—lactic acid."

Dr. Blass mentions that Neuwirth and Klosterman (*Proc. Soc. Exper. Biol. & Med.* 45:464 [Oct.] 1940) employed the ultramicro method for lactic acid developed by Muntz and myself, but he neglects to point out that subsequent to the development of this new technic Muntz and I determined the quantity of lactic acid in various types of carious lesions (*J. Dent. Research* 18:259, 1939). Later, in the course of investigations with Bradel on the metabolism of dental plaque material we demonstrated the production of lactic acid from dextrose by plaques (abstracts of the Dec. 30, 1939 Proceedings of the Subsection on Dentistry, American Association for the Advancement of Science, reprinted in *J. Am. Coll. Dentists* 7:80 [March-June] 1940; also see *Proc. Soc. Exper. Biol. & Med.* 45:104 [Oct.] 1940). We have also shown the capacity of dental plaque material to produce lactic acid from dextrose, fructose, sucrose, maltose and starch (*J. Dent. Research* 19:473 [Oct.] 1940).

Dr. Blass appears to stress a point of no great significance, i. e. the well known ability of certain oral micro-organisms to produce lactic acid. The important problem is to establish the precise role played by this acid in the chemopathogenesis of

human dental caries. We have developed a sufficiently sensitive and specific lactic acid method for investigation of the role of lactic acid in dental caries. However, despite the investigations conducted with this method here, we feel that the question is still unanswered. For the time being it seems best to regard the lactic acid produced by oral micro-organisms or dental plaques as an index of their metabolic activities rather than as the only proved agent in the chemopathogenesis of dental caries.

Clinic and the Department of
Medicine, University of Chicago.

AMERICAN FEDERATION FOR CLINICAL RESEARCH

To the Editor:—The organization of a society to be called the American Federation for Clinical Research has been proposed, and the idea is meeting with an enthusiastic reception. It is to be a society of young men and women interested in and carrying on clinical investigation. There will be two classes of membership: (a) club and (b) individual. A club membership is for any group of persons concerned with investigation in clinical medicine or allied sciences. An individual membership is for any one who has completed a meritorious investigation in these fields and is interested in continuing investigation. It is proposed to limit admission to individual membership to persons under 40 years of age. "Clubs" may be formed with membership of any age at clinics, hospitals or medical schools acting individually or as groups in cities, states or provinces or groups of states of the United States and Canada. "Clubs" will meet as frequently as seems desirable. There will be one general meeting with a scientific program, held in rotation in different parts of the United States and Canada. Annual dues probably will not exceed \$1. The organization meeting will be held at Haddon Hall, Atlantic City, N. J., on Monday, May 5. For those desiring to become individual members application blanks will be sent on request, mailed to Dr. Henry A. Christian, 1731 Beacon Street, Brookline, Mass., who is acting for a group of fourteen physicians who in 1908 participated in the organization of the American Society for the Advancement of Clinical Investigation. Questions regarding club membership may be similarly addressed.

HENRY A. CHRISTIAN, M.D., Brookline, Mass.

TUBERCULOSIS CARE AT BELLEVUE

To the Editor:—In Queries and Minor Notes (THE JOURNAL, Dec. 28, 1940) your correspondent conveys a misapprehension of practices at Bellevue Hospital in the treatment of Negroes with tuberculosis. In the Tuberculosis Service of this institution uniform criteria are followed in all cases in the use of collapse therapy. Among these criteria is an estimate of the patient's natural resistance, and it sometimes happens on this account that collapse therapy is used earlier for a Negro than it would be for a white patient with a similar lesion. On the other hand, the proportion of cases of acute pneumonic tuberculosis admitted to this service is higher among Negroes than among white patients. It is generally understood that the indiscriminate employment of collapse therapy for such forms of the disease may be harmful rather than helpful; therefore artificial pneumothorax and other mechanical procedures, when indicated, are used with extraordinary caution; in many cases such treatment is postponed until the acute inflammatory reactions have subsided.

Connecticut Homeopathic November Report

Dr. Joseph H. Evans, secretary, Connecticut Homeopathic Medical Examining Board, reports the written examination for medical licensure held at Derby, Nov. 12-13, 1940. The examination covered seven subjects and included 70 questions. An average of 75 per cent was required to pass. One candidate was examined and passed. The following school was represented:

School	PASSED	Year Grad.	Per Cent
Hahnemann Med. College and Hospital of Philadelphia	(1940)		78.5*

One physician was successful in the oral examination held for endorsement applicants at Bridgeport, October 15. The following school was represented:

School	PASSED	Year Endorsement Grad.	of
New York Homeopathic Medical College and Flower Hospital	(1930)*		Indiana

* License has not been issued.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Act (Texas): Only Holders of Unlimited Licenses Eligible for Reciprocity.—The Texas medical practice act requires all applicants for licensure to practice medicine, regardless of their school of practice, to possess substantially equivalent educational qualifications as to years of study and to pass identical examinations in twelve subjects named in the act. Successful applicants are then licensed to practice medicine and surgery without restriction. An applicant who possesses a license to practice medicine and surgery without restriction issued by a state having standards equal to the standards required by the Texas medical practice act may be licensed by reciprocity and without examination (Vernon's Ann. Civ. St., Art. 4500, as amended, Laws, 1939, p. 352).

The appellants, twelve osteopaths not residents of Texas, possessed Missouri licenses permitting them to practice osteopathy alone and to use drugs only to a very limited extent. They instituted proceedings to compel the State Board of Medical Examiners of Texas to issue them licenses by reciprocity. The trial court entered a judgment for the board and the osteopaths appealed to the court of civil appeals of Texas, Austin.

The osteopaths admitted on appeal that they were not entitled to licenses by reciprocity but they contended that the Texas board had issued licenses by reciprocity to nonsectarian physicians possessing licenses to practice medicine and surgery in Missouri, and that the Missouri medical practice act did not impose standards equal to those imposed by the Texas act in that the Missouri act requires applicants to submit to examinations in only seven subjects while the Texas act requires examinations in twelve subjects. This, the osteopaths contended, constituted a discrimination against them in violation of Article 16, Section 31, of the Texas Constitution which provides that the legislature may pass laws prescribing the qualifications of practitioners of medicine in the state "but no preference shall ever be given by law to any schools of medicine." Since the osteopaths, said the court of civil appeals, have admitted that they have no right to a license by reciprocity, we do not know on what theory they have any right to maintain proceedings of this sort. Manifestly, the decision by this court as to licentiates of the Missouri "allopathic" school who have been issued licenses by reciprocity by the Texas board cannot bind such licentiates because they are not parties; and neither the osteopaths nor this court have any right to require or has entered a declaratory judgment affecting future applicants for licenses by reciprocity.

The osteopaths argued that the effect of the board's action when it licensed by reciprocity "Missouri allopaths" and refused such licensure to Missouri osteopaths amounted to a violation of the constitutional provisions referred to, in that such action was tantamount to saying that if an applicant possesses a license to practice osteopathy only in Missouri he cannot receive by reciprocity a license to practice osteopathy in Texas, thus making the osteopath's right to a license by reciprocity dependent on whether or not he could practice any and all of the healing arts. The Texas legislature, answered the court, in accordance with the constitutional mandate has provided for examinations relating to all who desire to practice medicine, which examinations are the same with respect to all schools of medicine, and such requirements do not prefer any school of medicine in contravention of the constitution, because they apply to all persons alike. The Texas statutes simply define a "practitioner of medicine" and require him to pass certain examinations touching his qualifications before he may obtain a license to practice any art of healing. When so licensed he may practice all of the arts of healing, without regard to any school of medicine to which he may belong. Manifestly, he cannot contend that, because he belongs to a certain school of medicine or does not desire to practice all of the arts of healing, he may take only such examinations as he may think will qualify him to practice one school of medicine or one art of healing. Nor does the fact that the statutes in question do not prohibit him to do so render them repugnant to the constitutional inhibition against the preferment of any one or more schools of medicine. The state constitution and statutes are not concerned with any particular school of medicine. They apply to all schools of medicine and to all persons alike, in that they provide that all who desire to practice medicine shall pass certain examinations relating to their qualifications, which entitles them to practice any one or all of the arts of healing. Nor does the fact that the defendant board has granted reciprocity licenses to some "Missouri allopaths" without examination discriminate against the appellants. These osteopaths do not possess the statutory requirements for a statutory reciprocity license and, having no right in the matter, they cannot complain of the action of the board as to others who possess other qualifications different from their own. The subjects of examination required of "Missouri allopaths" are not the same as those required of the Missouri osteopaths. And, suffice it to say, while Missouri allopaths are required to take examinations in only seven subjects, they are issued a license by the state of Missouri to practice medicine in all its phases, the same as the Texas license authorizes its practitioners to practice medicine in all its phases, although the Texas practitioner is required to be examined in twelve subjects. Whether the seven subjects in which the "Missouri allopaths" are required to be examined substantially cover the twelve subjects in which Texas practitioners of medicine are required to be examined is a matter within the jurisdiction of the defendant board; and there was no proof whatever that this was not true in the instant case.

Accordingly, the court of civil appeals affirmed the judgment of the trial court refusing to require the Texas board of medical examiners to license the osteopaths without examination.—*Ashby et al. v. Board of Medical Examiners of Texas*, 142 S. W. (2d) 371 (Texas, 1940).

Society Proceedings

COMING MEETINGS

Annual Congress on Medical Education and Licensure, Chicago, Feb. 17-18. Dr. W. D. Cutter, 535 North Dearborn St., Chicago, Secretary.

American Orthopsychiatric Association, New York, Feb. 20-22. Dr. Norville C. La Mar, 149 East 73d Street, New York, Secretary.
Central Surgical Association, Ann Arbor, Mich., Feb. 28-March 1. Dr. George M. Curtis, Ohio State University, Columbus, Ohio, Secretary.
Mid-South Post-Graduate Medical Assembly, Memphis, Tenn., Feb. 11-14. Dr. A. F. Cooper, Goodwyn Institute Bldg., Memphis, Tenn., Secretary.
Pacific Coast Surgical Association, Los Angeles, Feb. 19-22. Dr. H. Glenn Bell, University of California Hospital, San Francisco, Secretary.
Society of University Surgeons, St. Louis, Feb. 14-15. Dr. Frank Glenn, 525 East 68th St., New York, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Bulgarian Belladonna and Amphetamine Sulfate for Parkinsonian Syndrome.—Davidoff and his collaborators used rabellon (a synthetic combination containing the same concentration of alkaloid as the most effective extracts of Bulgarian belladonna root) in combination with amphetamine sulfate for the treatment of 15 patients with postencephalitic and 10 with arteriosclerotic or idiopathic parkinsonism. Many of these patients had been subjected to various other therapies. Seven of the 10 patients with the postencephalitic type of the disorder were psychotic and only 1 with the arteriosclerotic type was thought to have a psychosis. The procedure for administering rabellon depends on establishing the optimal dose for the individual patient. This is done by increasing daily the dose of a fourth of a tablet once a day to a fourth three times a day

and then to half a tablet three times a day and so on. The patient is instructed to eliminate all alcohol, coffee and nicotine and to avoid meats, particularly spiced meats. When the minimal dosage that produces the optimal effect is established it is maintained thereafter. For patients who tolerate the drug poorly the dosage is not increased as rapidly. The appearance of mild toxic manifestations in these patients may be of value in indicating that the optimal dosage has been exceeded. After the patients had been maintained on a stable program of rabellon medication for several weeks, amphetamine sulfate medication was begun. The initial dose was 5 mg. in the morning and at noon. The dosage was increased at weekly intervals by increments of 5 mg. until the maximal of from 30 to 40 mg. was reached. The optimal dosage for many patients was 15 to 20 mg. daily. The dose of rabellon was decreased as the dose of amphetamine was increased. On the combination therapy 8 of the 15 patients with postencephalitic parkinsonism exhibited marked improvement, 3 moderate improvement and 4 no benefit; that is to say, 7 of the 8 without psychosis and 4 of the 7 with psychosis were favorably influenced by the therapy. Of the 10 with idiopathic and arteriosclerotic parkinsonism, 5 showed considerable improvement and 5 were unimproved. The patient with idiopathic parkinsonism with psychotic manifestations showed temporary amelioration but relapsed and was classified as unimproved. The results show that the combined therapy is superior to other forms of treatment.

Blood Sedimentation Test as Routine Diagnostic Procedure.—Agnor evaluates the sedimentation test from a study of the records of 2,063 patients with all types of disease. The test was performed as a routine procedure by a modification of the Westergren method. The one hour determination was considered to be the significant value, and a rate of more than 20 mm. was considered abnormal. The study indicates that the sedimentation rate is important enough to be employed as routine, as are blood counts and urinalyses in some diseases and serologic tests for syphilis. In the present series 176 cases, 8.5 per cent, showed changes in the serologic reactions of the blood. Similarly, 331 cases, 16 per cent, with abnormal blood counts gave specific information leading to the detection of the particular disease. Also in 207 cases, 10 per cent, the urinalysis gave specific information leading to a diagnosis. Therefore in 34.5 per cent of the cases the generally employed routine diagnostic tests were of specific value. On the other hand 702 cases, 34.1 per cent, showed an increased sedimentation rate, which although not specifically yet definitely indicated disease. Further analysis shows that of 1,549 patients with definite organic disease 681, or 43.9 per cent, had elevated rates; of the 514 without such evidence only 4 per cent had elevated rates. Among the latter patients were 5 instances in which the sedimentation rate was more than 30 mm. in one hour and 16 in which it was between 21 and 30 mm. The records of these 21 patients were subjected to a careful study; among them there was only 1 man, and he was discharged as a case of unclassified psychosis. He gave a history of having been treated in a tuberculosis sanatorium for eighteen months a few years before. Examination of the chest and of the sputum was negative, but tuberculosis may have accounted for the rapid rate. Of the remaining 20 patients with elevated rates, 10 were obese and for the other 10 there is no apparent explanation. There is no apparent association of obesity and increased sedimentation rate, but the coincidence was observed. Certain organic diseases seldom produce an increase in the blood sedimentation rate. Other diseases (chronic and acute infections, malignant conditions, localized suppurations and tuberculosis) may have an increased rate. The 1,549 cases in which there was evidence of organic disease were subdivided into cases of diseases usually associated with an increased sedimentation rate and a group in which such evidence was lacking. There were 85 cases with elevated rates in which the organic disease present is usually associated with a normal sedimentation rate. These 85 and the 21 previously mentioned represent 106 cases, 5 per cent of the series, in which an increased sedimentation rate was misleading. Therefore a sedimentation rate of more than 20 mm. in one hour was indicative of an organic disease of a type usually associated with an increased sedimentation rate in 95 per cent of the cases. An increased sedimentation rate in males showing no evidence of disease was observed only once. In general an increased rate in the male was more likely to be present with a disease usually associated with an increased rate than in the female.

Pulmonary Emphysema.—In studying the heart and pulmonary arterial tree in 32 cases of essential emphysema, Parker found that emphysema enlarged the right ventricle in 75 per cent and caused heart failure with decompensation in 44 per cent of the entire group. The severity of emphysema seemed closely correlated with the incidence of congestive heart failure as well as the frequency and extent of right ventricular enlargement. Some arteriosclerosis of the pulmonary arterial tree was observed among 80 per cent of the cases. Arteriosclerotic changes were noticed most frequently in the arterioles, and narrowing of the arteriolar bed was found in 66 per cent of the cases studied. The degree of obliteration of the arteriolar bed seemed influenced by the severity of the emphysema, yet there was no direct correlation between the degree of arteriolar sclerosis and that of the right ventricular enlargement, nor any relationship between the extent of the pulmonary arteriolar changes and the arteriosclerotic changes in the coronary arteries or the aorta. Therefore the author concluded that the arteriosclerotic changes of the pulmonary vessels in emphysema represent secondary manifestations of an existent hypertension within the pulmonary circuit which probably is produced by obstruction in the capillary bed. Although it may be assumed that when the degree of obstruction in the arteriolar system is great there is an augmentation of the pulmonary hypertension, it is doubtful that the amount of pulmonary arteriosclerosis usually seen in emphysema produces alone a serious obstruction to the pulmonary circulation.

Mucous Colitis.—White and Jones made a thorough clinical study of 60 patients with mucous colitis with the view of obtaining a basis for statistical deductions. Fifty-seven of the patients were studied psychologically in order to determine the role of precipitating emotional factors and personality types of the victims. Symptoms and signs of mucous colitis are constipation or diarrhea, abdominal cramps aggravated during peristaltic stimulation, palpable and tender sigmoid colon and certain minimal mucosal changes in the rectosigmoid as observed through the sigmoidoscope. Abdominal pain was the only constant observation. Mucous colitis may exist without abdominal pain. The disease usually has its onset in early adult life. The average age of the 60 patients at the onset of symptoms was 23.4 years. At the time of the study their average age was 35.8 years, indicating a long prediagnostic period. In 38 instances the original diagnosis was other than "colitis." Constipation at some time in the course of the illness was complained of by 80 per cent, diarrhea by 47 per cent. The percentages of other significant clinical observations were: stools of small caliber, 95; palpable colon, 88; pain on defecation, 81; pain related to food ingestion, 71; mucoid stools, 58; tensional headache, 66; dermatographia, 60; excess catharsis, 37, and needless surgery, 31. A number of conditioning factors seem to play a part in the production of its symptoms. Among them are direct irritants (rough foods, enemas, cathartics and infections of the colon), instability of the autonomic nervous system, general infectious diseases, sudden weight loss and physical "softness," specific food allergy and emotional tension. From the psychologic study of 57 patients the authors find that in most instances mucous colitis appears to be a somatic response to a type of nervous tension. Mental states conducive to this response appear to be anxiety, resentment and guilt. Associated depressive, neurasthenic and hypochondriac features are often present, but no one psychiatric diagnosis is predominant. A rigid type of thinking, similar to that seen in obsessive-compulsive states, is present in 50 per cent of the cases and may play a part in prolonging periods of tension. Symptoms of mucous colitis appear to represent a clear-cut somatic response to tension and not to be psychologically determined and obviously gainful, such as those seen in hysteria.

Tuberculosis in Nurses.—Myers and his colleagues present the observations begun in 1929 among student and graduate nurses in four schools on entrance and throughout their course of training, using college of education students as a control group. School 2 had no tuberculosis service and of 120 students under observation 18 were tuberculin reactors on entrance; 35 became reactors while in school, and 67 graduated as non-reactors. In 2 of the 18 who entered as reactors, pulmonary tuberculosis developed while in school; 1 of the 35 who later

reacted had a primary focus in the lung parenchyma demonstrated on roentgen examination. School 3 had no tuberculosis service, and here 204 students were observed; 50 were reactors on entrance, 43 became reactors while in school and 111 were graduated as nonreactors. In none of the reactors on entrance did demonstrable lesions develop while in school. Of those who became reactors, a primary focus in the lung demonstrable on the roentgenogram developed in 1 and bilateral clinical disease developed in 1 more than eighteen months after she was known to be a reactor. School 4 required a six weeks tuberculosis service of each student. Of 550 observed, 165 reacted on entrance, 204 became reactors while in school and 181 graduated as nonreactors. Of the 165 who entered as reactors, demonstrable lesions developed in 4 while in school and in 2 after graduation. Of the 204 who became reactors as students, lesions demonstrable on roentgen study or otherwise developed in 19 while in school and in 5 after graduation. In school 1 there was a twelve weeks tuberculosis service during the first part of the study, and of the 226 students observed 48 reacted on entrance, 137 became reactors while in school and 41 graduated as nonreactors. Of the reactors on entrance, lesions demonstrable on roentgen study or otherwise developed in 2 while in school or after graduation. Of those who became reactors, demonstrable lesions developed in 14 in school or after graduation. A questionnaire to schools 2, 3 and 4 in 1938 revealed that some of the nonreactors on graduation had since become infected and lesions demonstrable on roentgen study or by other methods had developed in a few. The authors believe that every reactor to tuberculin has one or more primary tuberculosis complexes in the body. In their group the number in whom lesions demonstrable on roentgen or other study have developed or who have become ill from tuberculosis is sufficiently large to make the problem a serious one. Of the students entering the college of education 24.8 per cent reacted to tuberculin, whereas on graduation 28.5 per cent reacted. Lesions which were demonstrated on roentgen examination developed in school in only 3 of 686 reactors. Obviously, the increase in the percentage of reactors depends on contact with contagious cases of tuberculosis. Throughout the study tuberculosis did not develop in a nonreactor to tuberculin. Their observation period is short for such a chronic disease, and therefore the authors think that more of the former students will fall ill from tuberculosis, especially as new cases have been reported annually. They do not believe that BCG has been proved sufficiently efficacious to solve the problem, as there is evidence of tuberculosis among some of the students so treated. In their opinion only a most rigid contagious disease technic provides a barrier and prevents the spread of tubercle bacilli from patient to student.

Sulfathiazole and Sulfapyridine for Pneumonia.—Garvin compares the results of sulfathiazole and sulfapyridine in the treatment of pneumococcal pneumonia; 40 patients were treated

with sulfathiazole and 62 with sulfapyridine. Five extremely ill patients of the first and 13 of the second group also received specific antipneumococcus serum. Five of the 40 patients treated with sulfathiazole died, as did 11 of those treated with sulfapyridine. Exclusive of the patients moribund on admission and who died within twenty-four hours, the corrected respective mortality is 10.3 and 8.9 per cent. The average age of the patients treated with sulfathiazole was 38.1 and of those treated with sulfapyridine 44.8 years. Treatment was begun in three and six-tenths days after the onset of the disease in the first group and in four and four-tenths days in the second group. An average of one and six-tenths lobes was involved among the patients receiving sulfathiazole and one and five-tenths lobes among those receiving sulfapyridine. There was no statistical difference between the two groups as to sex and color. There was a normal temperature within twenty-four hours among 14.3 per cent of the patients given sulfathiazole and of an additional 20 per cent within seventy-two hours. The respective figures for the other group were 13.7, 33.3 and 5.9 per cent. After the temperature had once reached normal, 71.4 and 78.4 per cent of the two respective groups of patients had a secondary rise above 99.5 F. In the majority of instances this was of no consequence. The average number of hospital days for the two groups was seventeen and four-tenths days. Two patients of the group treated with sulfathiazole had pleural effusion, 1 empyema, 1 slow resolution and 2 pulmonary abscess. Among the group treated with sulfapyridine, empyema occurred in 4, slow resolution in 1 and pulmonary abscess in 2. Sulfathiazole caused less vomiting but more crystals (61.5 as compared to 28.6 per cent) in the urine than did sulfapyridine. Otherwise toxic manifestations were not significantly different. Approximately twice as much sulfathiazole as sulfapyridine was required to maintain an average concentration of from 5 to 6 mg. of the free drug per hundred cubic centimeters of blood.

Acacia for Nephrotic Edema.—Goudsmit and Binger find that acacia can be incorporated advantageously into the regimen (salt-free, high protein diet, fluid restriction and diuretic salts) of the patient with nephrotic edema. Of 40 successive adult patients treated according to these principles, all but 4 were promptly relieved of edema. Failure of the treatment was usually due to the fact that the patient was unable to take sufficient nourishment and diuretic salts by mouth. Diuretic salts are not essential, as acacia may produce diuresis when used in conjunction with the diet. However, the best results are obtained if diuretic salts are included. Except in a few instances, mercurial diuretics can be dispensed with without sacrificing therapeutic results. Sometimes diuretics that are ineffective before treatment with acacia become effective after such treatment. Reactions after injection of acacia are infrequent and mild if care in preparation and administration is taken. The dosage in each course of treatment should be limited to from 90 to 150 Gm. divided in daily doses of 30 Gm. The acacia was usually administered as a 6 per cent solution in distilled water. Usually 500 cc. of the solution was given in one day. From forty-five to seventy-five minutes was allowed for its administration. It was given every day or on alternate days, whichever was tolerated better. As hepatic enlargement has not been observed, acacia may even be given to patients who have cirrhosis of the liver without further impairing its function. The decrease in serum proteins after injection of acacia is accounted for adequately on the basis of increase in plasma volume and concomitant dilution of its constituents. Renal insufficiency, secondary vascular disease or myocardial degeneration does not contraindicate its use. Its addition to the general regimen provides efficient results for the patient with nephrotic edema.

Multiple Primary Malignant Intestinal Lesions.—Since the report of Rankin and Barger in 1930, Schweiger and Barger collected from the records of the Mayo Clinic 23 cases of multiple primary malignant lesions of the large intestine. They divide them into two groups: those in which multiple cancers occur simultaneously (synchronous) and those which occur at different times (metachronous). Instances of multiple polyps of low malignant grades and single grossly carcinomatous lesions that were associated with single polyps of low malignant grade

were excluded. The possibility of implantation or extension from one lesion to another was precluded. The authors believe that many instances of multiple independent lesions in the intestine are probably not recognized. It is important to the patient that the physician exclude the possibility of other lesions, as some poor results after operation for cancer may be attributable to synchronous or metachronous lesions, unsuspected and therefore undiscovered. Curability by operative means will improve only as thorough diagnoses are made earlier. Only when a diagnosis of hemorrhoids is made after all other possible causes of intestinal bleeding have been excluded will the percentage of inoperable cases of cancer of the large intestine diminish. Once a patient has become the victim of such a malignant lesion he should watch for warning signs of recurring trouble. Many patients after having had a cancer of the colon removed assume erroneously that from that time forth they are immune to a similar morbid process. The pathogenesis of polyps may also explain the origin of cancer of the colon. Polyps play a role in the genesis of some cancers. The importance of a careful examination of the entire large intestine when cancer is found at any point is emphasized.

Vaginal Smear and Functional Sterility.—Rubenstein describes eight types of epithelial cells which most accurately reflect the gonadal hormone production in vaginal smears. The vaginal mucosa of children, old women and certain amenorrheic adult women is very thin and consists of basal layers of cells. These cells are characteristically round, somewhat larger than the large mononuclear leukocytes. In the nonpregnant woman they usually show various degrees of cornification. In the event of pregnancy the corpus luteum increases, and increasing amounts of theelin and progesterone are produced, in response to which cell types appear which may be used to diagnose preg-

nancy. Study of typical smears at various phases of the menstrual cycle shows that anovulatory cycles occur more frequently than heretofore supposed. The presence of infection or chronic irritation may invalidate the interpretation of vaginal smears and temperatures. Usually the vaginal smear and basal rectal temperature will show a discrepancy when some nongonadal influence affects one or the other; thus the combination of the two methods makes the other more reliable. The correlation between the temperature and gonad function is as follows: During the phase of follicle development and increasing theelin production, the basal rectal temperature drops progressively. The low point is reached just before ovulation, when conception is most likely. The temperature rise continues after ovulation and should exceed 0.5 F. in the first twenty-four hours and 1 F. the first week. As soon as the corpus luteum has regressed (a few days premenstrually) new follicles begin to develop. Theelin production begins again, although at a low level. Since there is now no functional corpus luteum, the temperature depressing action of theelin is again apparent. The temperature drops progressively throughout the premenstrual phase of the cycle. In the event of pregnancy, corpus luteum function persists and the postovulatory temperature rise is maintained. If temperature curves of previous cycles are available it is sometimes possible to detect a pregnancy before the period is missed, as the temperature remains high. The temperature and smear technics used together have proved to be as reliable in detecting early pregnancy as the Friedman test. By use of the smear-temperature technic it has been possible to classify three varieties of functional sterility. The commonest type of functional sterility is that in which the cycles are anovulatory, in which smears show marked desquamation characteristic of ovulation with no clear-cut and sudden rise in temperature. Instead the temperature rises gradually. In the amenorrheic anovulatory cycle there is no rise in temperature and the smears persistently show typical cells. A study of 739 cycles of 101 patients (66 of whom complained of sterility) showed that 338 seemed anovulatory; no patient was exempt from at least a single anovulatory cycle. Other causes of functional sterility are early abortion, failure of implantation and ovulation when coitus is avoided. In investigating functional sterility, attempts to determine the time of ovulation and any hormone deficiency in the preovulatory or postovulatory phase of the cycle and attempts to influence the cycle by appropriate therapy controlled by the vaginal smear-basal body temperature technic are indicated. If ovulation occurs, coitus is advised on the preovulatory and ovulatory days. If ovulation does not occur, therapy is directed to induce it. If the sterility is due to a deficiency in the corpus luteum phase of the cycle, luteinizing hormone or progesterone is indicated.

Effect of Belladonna on Appetite.—Greene observed that hunger could be controlled by belladonna and bromide or phenobarbital. He gave such medication to 39 obese patients, 5 with diabetes and overweight and 1 with chronic pyelonephritis with overweight. The medication was given the patients without their knowledge of its purpose. The appetite of 40 of the 45 patients was diminished after medication. The medication was an important factor in reducing the appetite, as 10 patients who omitted the medication of their own accord resumed it because hunger returned. The effect of the drug appears to continue indefinitely as long as the medication is continued. One of the patients with diabetes and moderate obesity is of particular interest. She was never able to control the diabetes because hunger caused her to eat between meals. Tincture of belladonna, 10 drops three times a day, before meals, eliminated this hunger and permitted the control of the diabetes. The patient with the pyelonephritis was forced to limit her activity because of the nephritis and hypertension, she began to gain weight and the administration of tincture of belladonna decreased her food intake sufficiently to stop the gain in body weight. Omission of the drug at a later date was followed by gain in body weight, and reduction again followed the administration of the drug. The cause of the

increase in appetite of patients with obesity is not known. Harrington and Newburgh have stated that many patients ingested food at frequent intervals because of nervousness or of habit. The author's observations support this contention and for this reason a mild sedative is of distinct aid in controlling the appetite of such patients. The fact that belladonna decreases appetite suggested that an alteration of the motility of the stomach or small intestine may be a contributing cause.

Chronic Bilateral Pyelonephritis and Hypertension.

Braasch and Jacobson examined 180 patients with chronic bilateral pyelonephritis to ascertain the possible role of chronic renal infection or its associated pathologic changes on the production of hypertension. The patients were subjected to a cystoscopic examination during which pyuria from both kidneys was revealed. Urographic data of 77 per cent of the patients were available and in all of them changes in the ureter, the pelvis or calices were demonstrable. Hypertension was considered present if the systolic blood pressure exceeded 145 mm. or the diastolic 90 mm. of mercury. Values for blood urea above 40 mg. per hundred cubic centimeters were considered above normal. Hypertension was present among 47, or 26.1 per cent, of the patients. This was an increase of 6 per cent over that found among a random control group. The increase was particularly prominent among patients less than 50 years of age; the incidence was almost twice that of the control group. The incidence among patients 50 or more years of age was approximately the same for the two groups. In identical age groups the incidence of hypertension was higher among those with pyelonephritis than that of the control group. An apparent relation existed between the incidence of hypertension and the duration of symptoms of pyelonephritis; the incidence usually increased with the duration of symptoms. However, the blood pressure of some patients remained normal after a history of pyelonephritis for from fifteen to twenty years. The highest incidence of a relation between the degree of pathologic change in the kidneys and ureters, as evidenced by the degree of deformity in the urogram and the incidence of hypertension, was evidenced by patients among whom the pathologic changes were most marked. Impaired renal function does not necessarily imply hypertension, as the blood pressure was normal among more than half of such patients. However, hypertension was found twice as often with impaired renal function as with normal renal function. Approximately 75 per cent of the patients with hypertension had a systolic blood pressure of less than 180 mm. of mercury and only 4 a systolic blood pressure of more than 200 mm. Thus the hypertension of these patients is usually of a comparatively benign nature. The usual micro-

organisms of the urinary tract were found. Among patients affected with *Aerobacter aerogenes* the incidence of hypertension was 38.5 per cent; this may be significant. The hypertension occasionally observed in mild or recurrent chronic pyelonephritis in which renal function is normal but no urographic deformity exists appears to be of independent origin and may be termed "essential hypertension."

Papillary Abnormality as Precursor of Renal Calculus.—Randall presents evidence to prove that three common urinary salts (phosphates, oxalates and uric acid) crystallize into primary renal calculi on a common, simple pathologic entity. By "primary renal calculus" is meant a small renal stone wherein (by current investigative means) one recognizes nothing responsible for its origin: no stasis, infection, hypovitaminosis, hyperparathyroidism or hyperexcretory state. Urologic studies offer two facts which aid materially in reasoning into the cause of primary renal calculus. They are that a calculus is of slow growth and its characteristic location of origin is in a minor calix. These facts suggested to the author that renal calculus is essentially a symptom of some morbid pathologic change that, in its turn, was the precalcenul or initiating lesion. In searching through 1,154 necropsies for such a lesion, the deposition of calcium salts in the renal papilla was revealed. This calcium salt deposit, when intrapapillary, is an incert replacement manifestation; but in its growth and if near the surface of the papillary wall it can lose its surface covering of epithelial cells through decubitus and then be bathed in caliceal urine. This is the nidus. This calcium plaque formation has been dissected out and calcium was present in the renal papilla in 19 per cent, nitrogen in 10 per cent and carbon dioxide in 1 per cent of the cases. Phosphorus was present but difficult to estimate accurately. A study of the incidence by decades and of 65 necropsy cases, also studied by decades, in which visible calculi up to 8 mm. in size were found adherent to a renal papilla, presents definite proof of the papillary origin of a primary renal calculus. The various salts which go to make different types of renal stone can so deposit and grow into a primary renal calculus. Calculi of differing salt compositions do have their origin from such pathologic changes in the renal papilla. Calculi supposed to be associated with hyperparathyroidism, hypovitaminosis, odd forms of renal infection, cases of nephrocalcinosis and so on belong to a separate and different form of papillary pathologic change associated with tubular inspissation of salts (calcium infarction) and represent the end results of hyperexcretory states.

Congenital Diaphragmatic Hernia.—Ladd and Gross report 25 cases of congenital diaphragmatic hernia encountered at the Children's Hospital. The early policy was to delay operation until the child was older, and of 9 such patients 5 are dead, 3 cannot be traced and only 1 is known to be alive. Of the 16 operated on since 1930, 9 have recovered. Seven of these are less than 1 year old. The youngest patient was operated on when 40 hours old. Of the 7 deaths, 1 occurred five days after a phrenicectomy before herniorrhaphy was attempted, and 1 four days after operation, probably from pneumonia. The remaining 5 deaths were probably due to one or a combination of the following factors: failure to provide proper fluid balance, lack of positive pressure anesthesia or too tight closure of the abdominal wall. The last factor, the failure of sufficient room in the underdeveloped peritoneal cavity to receive the abdominal viscera, has been solved by closing only the abdominal skin, allowing the abdominal wall to stretch and suturing the peritoneum and the rectus muscles at a second operation in five or six days. There is sufficient evidence to confirm the futility of expectant or medical measures. The policy of waiting until the child gets older and stronger is apparently responsible for the loss of a great many lives that might have been saved by a timely operation. The authors state that on a theoretical basis an operation performed in the first forty-eight hours of life is advantageous. They have had 2 such cases. Their experience has shown that these infants stand major surgical procedures far better than at the end of a week or ten days. Within the first two days there is the advantage of dealing with the intestine before it becomes distended, with the possibility of replacing it in the abdominal cavity—which might otherwise be impossible. Pre-operative treatment consists in making certain that the infant is in a proper state of hydration and that the intestine is deflated as much as possible. The latter can be accomplished by enemas, by gastric suction and by placing the infant in a tent with a high concentration of oxygen; from 90 to 95 per cent. Roentgen examination should always supplement the history and physical examination. A roentgenogram without the use of contrast mediums will usually give all the information that is necessary and is probably safer than giving barium to the baby.

Significance of Charcot-Leyden Crystals.—Thompson and Paddock examined the finger blood of 100 routine hospital admissions in which the diseases included hypertension, chronic nephritis, heart disease, pernicious and aplastic anemia, peptic ulcer, pneumonia, carcinoma, myelogenous and lymphatic leukemia, lymphosarcoma and Hodgkin's disease. The blood in none of these showed an absolute increase of the eosinophils and neither were Charcot-Leyden crystals demonstrated. Several patients were studied more thoroughly because of their disease or because of an unusual eosinophilia. Of 5 patients with bronchial asthma, none showed crystals in the blood. One patient with chronic ulcerative colitis had typical crystals in the stools but not in the blood. Of 3 patients with chronic myelogenous leukemia, 2 showed a number of crystals in the blood. The blood of 2 patients with presumed periarteritis nodosa showed Charcot-Leyden crystals in large numbers, as did that of a patient with presumed trichinosis with a leukocyte count of 16,000 and a 20 per cent eosinophilia. The blood of horses used for producing antiserum showed little eosinophilia and no crystals. The blood of normal rabbits showed no crystals even though their neutrophilic cells have an eosinophilic cast. Of 5 guinea pigs inoculated with *Trichinella spiralis*, none showed crystals. Prostatic secretion obtained after death produced no Charcot-Leyden crystals on standing for a week. After the addition of lead acetate to a filtered alcoholic solution of the secretion, quadrilateral crystals which resembled the crystals depicted in the literature as "spermin" were found. Microscopic examination of tissues from 11 fatal cases of myelogenous and lymphatic

leukemia revealed crystals in only 1 case; they were visible in all tissues of the body and were most plentiful in the pancreas and spleen. This patient had myelogenous leukemia. Of 7 patients with ulcerative colitis from whom sections of the colon were examined after death, 1 showed a marked increase of eosinophils in the submucosa, with occasional small Charcot-Leyden crystals. Slides of the lungs from 8 fatal cases of bronchial asthma showed crystals in 1; these were found in the mucus plugging the smaller bronchioles. Charcot-Leyden crystals appeared in blood in which a high absolute eosinophilia existed. They were not demonstrable by the same technic when eosinophils were not present in abnormally high numbers. The crystals are apparently not specific for any disease. The relation of the crystals to the eosinophils in all the diseases in which they were found seems to hold true. The nature of the crystals is not known. Attempts to isolate the crystals from the blood with a variety of solutions were unsuccessful; they were either dissolved or destroyed.

Infection with Virus of Choriomeningitis in Man.—Howard discusses diverse manifestations of 8 cases found among 33 with a variety of neurologic signs and a lymphocytic response in the spinal fluid. In 6 of the 8 the choriomeningitis virus was

isolated from the spinal fluid and after death it was found in the cerebral tissue of the remaining 2. The cases were divisible into infection without meningeal or neurologic signs, and benign lymphocytic meningitis and encephalitis, which may be mild, prolonged or fatal. The first case presented no neurologic signs and the complaint of persistent headache prompted the lumbar puncture, and the second case was a typical benign lymphocytic meningitis. The virus was isolated from these patients nine and five days, respectively, after acute onset. Encephalitis of varying severity was found in the next 4 cases. The third and fourth cases were relatively mild; recovery was fairly prompt and without sequelae. The onset was insidious in the fifth case and the course prolonged. Death was sudden in the sixth case. It occurred five months after onset, when improvement in the mental status was beginning to be noticeable. In the milder cases the virus was isolated from the spinal fluid early in the course of the disease; in the more severe and prolonged forms it was found as late as fifty-nine days after onset. Among these 6 cases the lymphocytic response in the spinal fluid was highest in the meningeal form of the disease. The cell count was within normal limits in the fifth and sixth cases; a positive Pandy or an increased protein content was demonstrable. Therefore it seems that the cell count is of no prognostic significance as to the seriousness of the disease. In neither instance of hemorrhagic encephalitis was the virus isolated from the spinal fluid. The pathologic picture in these two cases was that of widespread hemorrhagic lesions involving the subcortical white matter of the brain and cord in one and both the gray and white matter in the other. The meningeal reaction was slight and in both instances the choroid plexus was free. No inclusion bodies were found. The inoculation of fresh brain tissue into mice and guinea pigs from the seventh case failed to produce symptoms. The incubation period in the guinea pig and the chicken following inoculation with material held in glycerin for seventy days was long. This gives rise to doubt as to the validity of the observations. The later discovery that lesions were in the subcortical white matter prompted the author to try again with the small amount of remaining material. Work is now in progress to determine whether a latent or slowly developing infection in guinea pigs may be produced when the inoculating dose is small. From the data at hand this seems to be the case. A 10 per cent emulsion of brain tissue from the eighth case from the right temporal and right parietal lobes after storage in glycerin for seventy days produced fever in nine days in 1 instance and in fourteen days in 3 instances after combined intracerebral and subcutaneous inoculation into 4 guinea pigs. Death occurred eleven, twenty-three, thirty and thirty-seven days respectively after inoculation. Mice showed no evidence of infection and later succumbed to reinoculation with the Rivers W. E. strain. Failure to demonstrate neutralizing antibodies in the blood of the first and fourth patient is a source of concern, as the final proof is thereby lacking that the infection was really due to the virus of choriomeningitis. The spinal fluid of the other 25 patients, for whom a variety of diagnoses were later proved, was similarly studied and no virus was obtained. These served as controls and added to the evidence that choriomeningitis virus was not present among the stock animals in use.

Gastrointestinal Resections and Antianemia Potency of Liver.—Geiger and his co-workers tested the theory of liver storage of the antianemic principle by removing the stomachs from 7 swine and then determining whether their livers showed progressive depletion of the effective factor. The results of the experiments are summarized as follows: 1. Extirpation of the stomach in swine results in progressive depletion of the antipernicious anemia principle of the liver and complete exhaustion of liver potency within six months. This suggests that the liver stores or elaborates and stores a product furnished by the stomach. 2. Similar exhaustion is observed when the stomach is retained but isolated within the animal. This suggests that the effective factor results from gastric digestion rather than from an internal secretion of the stomach. 3. The livers of newborn pigs from a normal sow contain the anti-pernicious anemia principle, while those of newborn pigs from an agastrie sow do not. This confirms the view that the effective factor is a product of gastric digestion. 4. Extirpation of the duodenum in swine diminishes the liver's content of the principle, which indicates that the duodenum is a true source of Castle's intrinsic factor.

Pathogenesis of Nonpulmonary Tuberculosis.—Wilkinson discusses the relation between tuberculosis of the lymph nodes and hematogenic tuberculosis. He bases his remarks on the data obtained from 593 persons with nonpulmonary forms of the disease who between 1930 and 1937 were admitted to the Essex County Council Sanatorium, Black Notley. Skeletal tuberculosis was the most common form of nonpulmonary tuberculosis at all ages, renal tuberculosis developed most often in young men, tuberculous peritonitis was more common in female than in male patients and was most frequent in adolescence, and the majority of patients with lymphatic tuberculosis were children. Patients admitted with tuberculosis of the thoracic nodes are not included in the series. Nonpulmonary hematogenic tuberculosis or tuberculous bacillæmia was found to be evenly distributed, that is bilateral. Twenty-two of the 28 patients with renal tuberculosis had a complete examination and showed evidence of bilateral infection. Similarly tuberculous epididymitis was found to be bilateral in most patients, although it was not always manifest simultaneously in both epididymides. Nine of 13 patients suffering from tuberculous salpingitis were known to have bilateral disease. The author states that tuberculous peritonitis may occur as a direct extension from tuberculous abdominal nodes, but in his opinion it occurs more commonly as a hematogenic tuberculous infection or as an ascending peritonitis from tuberculous fallopian tubes. When the infection is hematogenic, miliary tubercle along the blood vessels may be seen at operation. Tuberculous pleurisy is a commonly associated lesion. It occurred in 6 of his patients. Of the patients with tuberculosis of the lymph nodes, 119 were admitted for tuberculous cervical adenitis and 40 for tuberculous abdominal nodes. No associated tuberculous lesions were found. Follow-up reports of 81 were received from a few months to seven years after discharge, and in no case had a fresh tuberculous lesion developed in another part of the body. The results of examination for evidence of past or present glandular tuberculosis in 134 patients suffering from skeletal, peritoneal or genito-urinary tuberculosis (diagnosed by roentgen evidence of calcification in the chest or abdomen) show no evidence of tuberculosis of the cervical glands; neither was there any gross evidence of past or present glandular tuberculosis. However, this does not mean that the patients did not suffer from some degree of lymphatic tuberculosis at the time of their primary infection, as in some patients the glandular tuberculosis may have subsided before the roentgenogram was taken or enough time may not have elapsed for calcifications to develop. The study shows that conversely patients with hematogenic tuberculous lesions do not necessarily show evidence of previous gross glandular tuberculosis. Therefore it may be inferred that gross glandular tuberculosis is not necessarily associated with severe tuberculous bacillæmia and may, on the contrary, be a means by which severe hematogenic tuberculous infection is prevented. It appears that the severity of hematogenic tuberculous infection is not proportional to the severity of glandular tuberculosis and that hematogenic tuberculous lesions are not likely to appear if the glandular tuberculous lesion following primary infection is treated by constitutional measures. Under favorable conditions the lymphatic system may afford some protection against the entrance of tubercle bacilli into the blood stream. Not only may the cervical, thoracic and abdominal nodes be a barrier to the blood stream entrance of tubercle bacilli from the site of primary infection, but the regional glands may exert the same function. The disastrous effects of tuberculous infection in infants are to some extent modified if the lymphoid tissue is well developed and if the child's environment and nutrition are good.

Perforated Peptic Ulcer.—Ross presents the follow-up data of 89 out of a personal series of 175 cases of perforated ulcer observed by him during 1930 to 1940. Fifty-one of the 89 patients have no symptoms and are following their previous vocation, 28 have trivial or occasional mild symptoms causing no inconvenience or loss of time from work and 10 have symptoms that are severe enough to cause absence from work. The follow-up suggests that, provided the patient adheres to a strict dietary for six months after operation and maintains dietetic care thereafter, his prospects are good. However, many symptom-free patients stated that they were taking no dietetic precautions. The patient's occupation often gives rise to difficulties, as lorry drivers, bus drivers, tram conductors and the like have not the same dietetic facilities as persons in other trades. In assessing the immediate outlook the number of hours between the perforation and operation is the most important single factor. Among the 175 cases there were 28 (16 per cent) deaths; in 19 of these the delay ranged from three hours to seven days; the average was twenty-five and a half hours. If 2 cases delayed for five and seven days respectively are excluded, the average period between perforation and operation among fatal cases was ten and four-tenths hours. The remaining 9 cases were simply described as "late." The site of the ulcer is another important factor; the perforated gastric ulcer is regarded as having a somewhat worse prognosis. The prognosis for duodenal, pyloric and juxtapyloric ulcers appears to be identical. While it has been generally recognized that perforation and hematemesis are usually fatal, it has been overlooked that any intercurrent disease renders the prognosis infinitely worse, irrespective of the two foregoing factors. In the author's series, among the deaths, it was established that before operation 6 patients had had angina, chronic myocarditis or auricular fibrillation, 2 chronic bronchitis, 3 diabetes mellitus, 1 chronic nephritis, 1 exophthalmic goiter and 1 syphilis. Thus in 50 per cent of the fatalities an intercurrent disease was present. The most dangerous period appears to be three or four days after the operation, death being probably due to peritonitis and toxemia. The operation should consist of simple closure of the perforation and removal of the peritoneal fluid, together with drainage through a suprapubic stab incision when the fluid is thick, and in late cases. Gastro-enterostomy at the original operation is contraindicated because the operation is unjustifiably lengthened; the perforated ulcer may be of the "acute" type and, should a subsequent operation become necessary, a gastroenterostomy is rarely the wisest and most efficacious procedure.

Galvanotherapy in Poliomyelitis. H. Bordier.—p. 746.

Penetrating Wounds of Thorax.—Monod discusses treatment of pleuropulmonary uncomplicated wounds of average gravity. These constitute 30 per cent of all chest wounds incurred in war. He classifies three types and indicates the nature of the intervention: (1) lesions accompanied by serious hemorrhage; (2) lesions presenting the risk of infection due to presence of shell or bomb fragments and (3) uncomplicated cases. If in spite of sedative medication and immobilization a progressive aggravation is observed, intervention is indicated. Open chest wounds can be enlarged to determine the source of the hemorrhage. In closed chest wounds or those presenting small perforations, whether thoracic or extrathoracic, a wide exploratory thoracotomy is in order. Hundreds of cases of the second type proved at necropsy that enclosed shell or bomb fragments presented a serious risk of infection. In the determination of the operative procedure, great importance is attached to the embedded foreign body itself, to roentgen ray evidence and to presence of costal and scapular fractures. Wide thoracotomy is to be performed, especially if fragments are lodged juxtapleurally and fractures are involved. In uncomplicated cases thoracotomy is delayed and watchful observation is practiced. Excision of the parietal wall wound is always to be made no matter how insignificant the cutaneous lesion may be for a great deal of muscular damage may be concealed. Respiratory disorders need to be noted, frequent bacteriologic tests made and drainage promptly applied. Pleural infection may occur in the absence of a hemothorax. High initial pyrexia has a tendency to fall spontaneously. Men with thoracic lesions should be assigned to a special service division where they may receive further care for empyema and where secondary removal of foreign bodies may be performed. Evacuation should not be attempted until the end of the second week. The author cautions that a badly supervised empyema will lead to pleural fistula and a chronic condition which necessitates serious surgical intervention. He stresses the fact that thoracic wounds require medical care until the wound has completely healed.

Treatment of Bronchiectasis.—According to Santy and Latarjet, a study of the recent, especially the English and American, literature discloses the progressively favorable results, immediate and late, obtained by lobectomy and pneumonectomy in bronchiectasis. The prognosis, the value of conservative preoperative treatment, the indications and the contraindications for surgical intervention are increasingly better understood. Spontaneous recovery, under conservative management, can be expected only in "dry" cylindric cases of bronchiectasis resulting from a previous infection. Some "dry" hemoptysic cases in which roentgenograms taken with a radiopaque substance (iodized oil) and the endoscope reveal lesions need promptly to be surgically treated. In spite of their apparent benignity, these cases invite new hemorrhages and secondary infection of the cavities. The essential service of conservative therapy, working with appropriate clinical and laboratory controls, lies in conditioning the infected patient for the operative act. The mortality incidence for partial pulmonary extirpations extending over ten years amounted to 10 per cent of the cases treated. Subsequent series have been without a single fatality in the experience of some authors. The mortality rate for total extirpation was from 18 to 20 per cent. Children were observed to tolerate both operations better than adults. In 166 cases of lobectomy, cited from Tudor Edwards, involving 38 children aged from 4 to 16 years, there were no deaths (0.0 per cent). In 16 adults aged from 40 to 50, there were five deaths (31 per cent). In a summary of 239 cases (lobectomy and pneumonectomy) collected from different authors, 172 were completely restored functionally and anatomically (70 per cent) and good results were obtained in patients restored to normal living but requiring subsequent medical attention. In the latter group the roentgenogram was either unable to detect residuary lesions or iodized oil pene-

tration was insufficient, especially in the lingular process of the left upper lobe. The authors discuss the value of postural drainage, the indications for one stage and two stage interventions (preoperative artificial creation of adhesions), the value of early diagnosis and the need of complete radiopaque delineation of the whole bronchial tree in both lungs. Localized bronchiectasis will yield only to surgery. Mortality resulting from pulmonary exeresis is chiefly due to infectious complications.

- *Germ Cell Damage from Roentgen Irradiation. C. Salgado and J. Ferolla.—p. 391.
Hormone Therapy in Gynecology: Some Aspects. F. V. Rodrigues.—p. 418.

Germ Cell Damage from Roentgen Irradiations.—Salgado and Ferolla review the literature on the clinical application of gynecologic roentgen irradiation and the possibility that the latter may cause harm to germ cells. They refer particularly to the work of Muller, which proved the existence of roentgenologic changes in "Drosophila melanogaster." The changes attributed to roentgen irradiation correspond to a condition defined as early germ cell damage. A late genetic damage has not been proved so far. Its demonstration would interdict gynecologic irradiation, but this does not seem to be the case. The authors irradiated the lumbar region of rats with doses of from 2.4 to 5.6 roentgens. Sixteen days later the animals were given to the males. The first generation consisted of 52 animals, all normal in appearance, conformation of the eyes, development of the body and behavior. The rate of mortality in the animals was the same as in the offspring of nonirradiated animals. By the end of the experiment a total number of 118 adult rats from the irradiated original ancestors were obtained in five consecutive generations. Through the generations all the animals were normal in all respects and procreated by endogamy.

- Treatment of So-Called Prostatic Adenoma. A. Madrid.—p. 89.
*Poisoning with Barbituric Acid Compounds. R. Leñero.—p. 97.

Strychnine in Poisoning with Barbituric Acid Compounds.—Leñero reports encouraging results from large doses of strychnine in more than 100 cases of acute poisoning with barbiturates. The treatment should be commenced as early as possible in doses of 200 mg. for the first two hours, up to a total of 1,300 mg. for the first twenty-four hours. The drug is administered intravenously in isotonic dextrose solution. The acuteness of the condition when the victim is first seen, age, abnormalities of the viscera, pregnancy and the presence of associated poisoning do not contraindicate its use. The degree of saturation with the drug in the course of treatment is appreciated by the Chvostek sign. The author concludes that strychnine in large doses should be resorted to immediately in cases of barbituric coma, as well as in accidents during administration of evipal soluble and similar barbituric anesthetics.

*So-Called Irritable Soldier's Heart. D. Thomas.—p. 989.
Clinical Significance of Sternal Puncture. S. Thaddeus.—p. 992.

Irritable Soldier's Heart.—Thomas points out that a healthy person experiences dyspnea during physical exertion which persists for varying periods. After long and severe exertions, signs of exhaustion appear in the form of tremor, weakness and later of fatigue and pain. Pulse rate and blood pressure are increased, respiration is accelerated, the apex beat is often prolonged and forceful, and systolic murmurs are frequent. These are signs of the physiologic effort syndrome. This syndrome develops more readily in weak persons than in the average person. It is frequent in young soldiers but is not a specific soldier's disease. The so-called irritable soldier's heart is one of the ordinary chronic defects of city dwellers who lead sedentary lives. It is erroneous to designate this defect as

heart disease. The majority of such persons are emaciated and have weak muscles and a long and narrow chest. Some are nervous as indicated by the ease with which their emotional reactions are elicited. The author examined functional capacity of the heart of men with so-called soldier's heart by means of Rein's basal metabolism recorder. He found that men with soldier's heart differ from normal men by a lesser utilization of the ventilation oxygen, great alterations in the respiratory volume, prolongation of recovery time for respiration and slight utilization of oxygen. It is difficult to estimate the functional capacity of the so-called soldier's heart. Many of these men are weak and incapable of great physical exertion. The history often reveals that during the years of growth they had been excused from physical exercises partly because they failed in great exertions and partly because a systolic murmur had been regarded by the physician as indicative of heart disease. This classification as a sufferer from heart disease had an unfavorable psychologic effect. It is a mistake to keep these men away from all physical exertion. Cautious and gradually increasing physical exertion often accomplishes good results. These persons should not exert themselves to a point at which they feel exhausted, but long enough for the respiration to become noticeably accelerated and deepened. The author found that men in whom signs of soldier's heart are mild or moderate can be developed into capable soldiers.

Prognosis of Obesity.—Grafe cites statistics which indicate that life expectancy of obese persons is less than that of persons of normal weight. This should be impressed on obese persons in order to give them the will necessary for the effective treatment. If the age of 40 is taken as the starting point, the chances to reach the age of 80 are only one third as favorable in the obese as in those of normal weight. Obese octogenarians are a great rarity. It is necessary to differentiate between what is theoretically attainable and what can be accomplished in view of human shortcomings. Theoretically obesity is curable, even in the severe cases, as far as no irreversible changes have yet developed. Obesity develops as the result of a positive energy and water balance and it can be counteracted only if these balances are negative for a long time. The dietetic treatment is most important; the nutrition must be subnormal in calories. In the beginning it should provide 30 per cent of the requirements and less and should gradually be increased to from 50 to 75 per cent. Many begin with a fasting cure. The author usually begins the reducing treatment with a fast of several days' duration, but he thinks that it is never necessary to continue this fast for two or three weeks. Whether to extend the days of fasting depends chiefly on how the patient reacts to hunger and what his mental attitude is. There are no strict contraindications, but no patient should ever be forced to fast. In prescribing a diet it is essential that the patient be given exact quantitative regulations with careful computation of calories, and the patient must carefully weigh all the food. The fluid and sodium chloride intake must also be carefully controlled, because the adipose patient is not only lipophil but also hydrophil. The total fluid intake should not exceed 0.75 liter and the salt content must be reduced to the point at which the food remains just eatable. Medicinal therapy is necessary in some cases. Salyrgan is helpful in counteracting the hydrophilia of the obese person. The diuretic effort can be intensified by acidification of the organism with ammonium chloride. In severe cases of obesity, particularly in those in which endogenic or constitutional factors are involved, thyroid preparation can be given. Contraindications to this treatment are severe organic cardiac defects, glycosuria and diabetes. There are hopelessly careless obese persons who lack the will power for effective treatment, but there is no incurable obesity. There are patients who, in spite of rigorous dieting, do not lose much. These patients lose

fat, but they retain water, so that the weight remains unchanged for days or weeks. However, later this water is eliminated either spontaneously or with the aid of diuretics.

*Has Roentgenologic Diagnosis Improved the Therapeutic Results in Gastric Cancer? H. Bade.—p. 114.
Increase in Conduction Capacity of Water by Action of Roentgen Rays. R. Reiter.—p. 122.

Roentgenologic Diagnosis of Gastric Cancer.—Bade studied 107 patients with gastric cancer in order to determine whether the improvement in roentgenoscopy produced better therapeutic results. He chose patients under 40 because of a greater possibility of error among younger patients. He found that there was no increase in the number of operable cases despite the fact that 75 per cent of patients with gastric carcinoma have a long history of gastric disorders. An early roentgenologic examination by one experienced in this technic is of great importance. Control examinations to check negative results are necessary but are rarely carried out. There is danger of erroneously diagnosing cancer as ulcer, for their roentgenologic differentiation is often impossible. The differentiation may be impossible even at operation. It is advisable for this reason to resort to resection if the niche fails to decrease on a dietetic regimen. Tumors which appear benign in the roentgenogram should be operated on, because of the possibility of differentiating with certainty benign from malignant tumors. A roentgenologically detected ulcer subjected to dietetic treatment requires control examinations. Should the niche fail to decrease, gastric ulcer in contradistinction to duodenal ulcer should be resected early. A carcinoma may exist even if the niche decreases and the patient is free from complaints. The author observed one such case. The author is convinced that the extremely unfavorable therapeutic results can be improved if polyps and other benign tumors are accepted as an indication for an operation.

*Fever Therapy of Poliomyelitis. H. Kohl.—p. 278.
*Congenital Tuberculosis. E. Keyser.—p. 284.

Fever Therapy of Poliomyelitis.—Kohl subjected in 1936 2 children with poliomyelitis to two series of fever treatments, the fever being induced by a bacterial protein preparation. The results of this form of fever therapy proved unsatisfactory. He treated 8 children with poliomyelitis with malaria. The fever treatments with the bacterial protein had been given two and three months after the onset of the poliomyelitis, and the malaria therapy from three to six weeks after the onset. In spite of the earlier treatment, however, the results were not encouraging. The author gained the impression that the same improvement in motion might have been obtained with the measures customarily employed at the Leipzig clinic. He reports histories of children subjected to malaria treatment and shows that at most in 3 cases a slight improvement might have been due to the fever therapy.

Congenital Tuberculosis.—Among 79 tuberculous nurslings Keyser observed 1 in whom the disease was definitely congenital. This child was born to a mother who had a productive, infiltrative pulmonary and laryngeal tuberculosis and who died from tuberculosis one month after the birth of the child. The infant had been removed from the mother immediately after birth and was cared for in an environment free from tuberculosis. The child developed normally the first three weeks after birth, at which time fever and nutritional disturbances appeared. Roentgen examination revealed a bilateral, coarsely nodular pulmonary tuberculosis, and the gastric juice contained tubercle bacilli. The child died on the thirty-fourth day of life, and the necropsy disclosed a bilateral, caseous, nodular pulmonary tuberculosis with involvement of the hilar

lymph nodes. The history and anatomic features of the case indicate a congenital or at least congenital character of the infection. The anatomic picture was typical for cases of this type when compared with the 5 cases reported in the literature. All these infants had a disseminated, nodular pulmonary tuberculosis. In all of the cases the primary focus could not be demonstrated. The author assumes that this disseminated nodular pulmonary tuberculosis of the first two months of life, in which it is impossible to find a primary focus, represents a primary colonization of tubercle bacilli which can take place only by way of the bloodstream or by the aspiration of amniotic fluid containing tubercle bacilli.

Rheumatic Articular Disease and Trauma. G. Jorns.—p. 865.

Rheumatic Articular Disease and Trauma.—Jorns points out that rheumatic changes in one or several joints are sometimes ascribed to accidental injuries. The assertion is often based on mere conjecture. The author presents a survey which indicates the deviousness of the attempts to deduce from the presence of a locus minoris resistentiae supposedly produced by a trauma, and the possibility that pathogenic organisms circulate in the blood. He thinks that it is more feasible to accept individually differing association rather than generally applicable relations. The factors leading to the development of pyogenic metastases should be looked for not only in the type of the pathogenic organism but also in the patient's body and here less in the local tissue injury than in the general status of susceptibility. In view of the predisposition of rheumatic infections for the joints, the action of a preceding trauma can be regarded as dispensable. Moreover, it would have to be explained in what manner the traumatic injury produces the prerequisites for the development of rheumatic articular changes. This question is pertinent in view of the fact that the morphologic aspects of rheumatic polyarthritis are such that the association of trauma can be dispensed with. Before more is known about the cause of rheumatic infection, caution is necessary in the evaluation of a possible connection between trauma and articular rheumatism. A causal connection can be accepted only if the following prerequisites are fulfilled: 1. The rheumatic process must develop in the injured joint. 2. Considerable force must have been exerted. 3. The rheumatic lesion must correspond with the trauma in location as well as in time. The author points out that if trauma and infectious rheumatic process concur there is the danger that the direct results of the trauma are regarded as rheumatic and are treated incorrectly.

Diagnostic Errors and Curiosities in Tuberculosis Clinic. F. Lommel.—p. 401.
Conservative Obliteration of Varicose Veins or Surgical Procedure? J. Neideck.—p. 403.

Conservative Treatment of Varices.—Neideck recommends sodium chloride injections in the treatment of varicose veins. The technic consists in injecting not more than 20 cc. in toto of a sodium chloride solution (1:3 concentration) into varices at intervals of three days. Puncturing is done distally, slowly proceeding in an upward direction, with the patient in a sitting position. Troublesome phlebitis can be prevented by the utmost cleanliness in the instruments and in disinfection of the skin. Venous impermeability, damaged renal parenchyma, staphylococcosis and the presence of febrile disease or of a thrombophlebitis are contraindications. In pregnancy, a gynecologic examination should be made first. Reactions to injections vary from case to case, since the destruction of the varicose channels is not always the same. The danger of paravenous infiltration may be met by promptly injecting from 10 to 20 cc. of the patient's cubital venous blood into the endangered tissue area or by a saline solution. The author believes that the conservative treatment of varices does not yet enjoy the consideration which it deserves.

*Roentgen Therapy in Dementia Paralytica and Tabes. F. Bering.—p. 1066.
Things to Be Observed by the Practical Physician in Examination of Gastrointestinal Diseases. R. Kühn.—p. 1068.

Chemotherapy in Gonorrhea.—Schreus discusses the use of various sulfonamide preparations in gonorrhea, the dosage, prevention of relapses and sequels. Nothing is gained by including hours of the night into a therapeutic program which provides for three to four single daily doses. Concentrated doses given orally for three to five days are sufficient to produce a cure, if a cure is possible. Cases which respond slowly to drug action, though negative after long-continued medication, are often liable to relapses in the end. Massive doses given over a shorter period of time are better tolerated than those of lower concentration administered for a longer time. Drug treatment, routinely continued for prophylactic purposes after the patient has been demonstrated to be gonococcus negative, is unnecessary and harmful. Optimal dosage is regarded as consisting in the compatibility of high concentration levels with the ability of the patient to tolerate them. Actual cure is determined by the absence of the micro-organism in cultural assays. In addition, two provocative tests are applied, one immediately after the conclusion of the treatment, the other a week later, and the patient is kept under clinical and laboratory observation for two weeks longer. To induce abundant urinary excretion, compound solution of iodine in a 1:6 concentration was found effective. A refractory tendency to sulfonamide therapy in primary gonorrheal infection is now met by vaccination or by nonspecific stimulation ten days before the drug treatments are begun. Sequels were few and negligible. Hepatic damage, originally observed in a few cases, in subsequent investigations was no longer determinable by relevant laboratory examinations. Cyanosis was not equally induced by the various preparations and is possibly due to the aniline element in the sulfonamides. It readily yields to methylthionine chloride. Chemotherapeutically stubborn cases were often seen to react remarkably well to local treatment when local treatment was applied concomitantly or soon after the termination of the other treatment.

Roentgen Therapy in Dementia Paralytica and Tabes.

—Bering summarizes two years of observations of the value of roentgen therapy in dementia paralytica and tabes, based on 130 cases. Cranial application of irradiation to patients with dementia paralytica was suggested by the favorable results obtained roentgenologically on abscesses of the axillary apocrine glands. The case material consisted of persons in whom malarial therapy was either contraindicated or had to be discontinued because of cardiac disorders or had left sequels such as headache, malaise and lassitude. The efficacy of roentgens is conditioned on the extent to which anatomic changes, both inflammatory and degenerative, have taken place in the brain. These cannot always be determined. The meninges are more or less strongly indurated. The radiosensitive endothelial cells show proliferation and edema in the vessels of the cerebral cortex and in the larger vessels. All portions of the brain are pathologically affected; the frontal most, the occipital least. The particular considerations entering into the management of each case are governed by the clinical and cerebrospinal fluid observations. No definite conclusions can yet be formulated regarding the usefulness of roentgen therapy in dementia paralytica. In a number of cases subjective and objective amelioration was achieved which still persisted after eight months. In general, irradiation was found to have an effect on the clinical manifestations of dementia paralytica, especially in incipient stages, and on the cerebrospinal fluid comparable, at least, with that of malarial therapy and hence applicable in cases in which the latter treatment is not permitted. Moreover, its action was more prompt. Lymphocytes in the spinal fluid were observed to decrease rapidly. The patients often gained weight. Often headaches and malaise were cleared up and the memory was seen to improve, the roentgens thus favorably influencing inflammatory sites that had not responded well to malarial therapy. Roentgen action on the frontal lobes not infrequently clarified the mind, increased the appetite and stimulated the desire to

work, as the result, no doubt, of the favorable effect on the augmented endothelial cells of the endarteritic processes. Roentgen therapy is not intended to replace malarial therapy. Best results are obtained in early diagnosis. There are no contra-indications to the treatments. Outpatient service does not interfere with the economic life of the patient. A temporary complete loss of hair must be reckoned with. Roentgen therapy for tabes was not encouraging, though some favorable results were achieved.

Early Diagnosis and Treatment of Carcinoma of Colon.

—According to Graff the unusually frequent concurrence of polyps and carcinoma of the colon is significant and necessitates careful examination and continued observation. Polyposis is often hereditary and the carcinomatous degeneration is likewise frequently a familial trait. Colon carcinoma is amenable to a complete surgical cure, because it grows slowly and metastasizes late; but, in spite of this, a high percentage of carcinomas prove inoperable at the time of operation. The results of surgical treatment could be greatly improved by earlier diagnosis. There are three stages in the carcinoma: (1) the stage of clinical latency, (2) the stage of gastrointestinal manifestations and (3) the stenotic stage. During the first stage the diagnosis is always more or less accidental. The correct interpretation of the symptoms of the second stage decides the fate of the patient. Only a few of the symptoms are associated with the focus of the disease. General discomfort, fatigue, feeling of fullness and of pressure after eating and flatulence are the chief symptoms. Pallor, gastric disturbances and occasional colics complete the picture of the early second stage, but gradually stenosis develops and this considerably facilitates the diagnosis. If operation were done during this stage, it would still have a favorable prognosis. Conservative treatment is justified only when carcinoma can be definitely excluded. Especially the comparatively mild disorders of incipient stenosis with spasmodic pains in the abdomen, irregularities of the formerly regular defecation, meteorism, pallor, mild anemia and loss of weight must be taken as strongly indicative of colonic cancer. They make it imperative to use all diagnostic aids. Clinical examination by means of inspection and palpation should be complemented by laboratory tests. The examination of feces for mucus and blood may be valuable, but only identical results in repeated examinations are reliable. Mild hypochromic anemia and occasional leukocytosis are suggestive but by themselves are of no particular value. The same applies to the sedimentation speed of the erythrocytes. Although it is often greatly increased in malignant tumors, it is not necessarily so. The outcome of cancer reactions likewise cannot by themselves be taken as an indication for operation. The most important diagnostic measure is the roentgen examination with the best available apparatus and technics and with various exposures. Even this method has its limitations. Incipient carcinomas without ulcerations, and small carcinomas hidden behind a fold of mucous membrane may escape detection. Moreover, the differentiation of benign and malignant stenoses and the exclusion of spasm is often difficult. Exploratory laparotomy should be resorted to, after all other examinations have failed and yet colon carcinoma is suspected. Alternate diarrhea and constipation, loss of weight, admixture of blood and mucus to the feces and persistent contraction of the intestine above the stenosis are usually regarded as the cardinal symptoms, but the author points out that they are not present in more than 60 per cent of the cases. Ileus is the most frequent and the most feared complication. Abscess is another dangerous complication. Intense peristalsis may cause early

invagination of a small tumor. Severe hemorrhages resulting from the erosion of vessels are rare, but perforation into a neighboring organ is more frequent. In spite of the fact that some patients succumb to a radical operation, this intervention deserves a wide application, because all palliative operations are of slight value. They prolong life for only a few months, during which the patient suffers intensely. In the presence of ileus a fistula must first be made. The operation is thus performed in three stages. In carcinoma of the transverse colon and of the loop of the sigmoid, the Mikulicz method of exteriorization can be successfully employed. In carcinoma of the colon on the right side (cecum, ascending colon, hepatic flexure and right transverse) the one stage operation is the method of choice.

 Case of Vaccine Pustules on Eyelids Treated with Sulfapyridine. V. Larsen.—p. 1096.

Peripheral Facial Hemispasm.—According to Jessen, peripheral facial hemispasm is a well defined disorder depending on irritation of the facial nerve. When in some cases an etiologic agent can be established it is most often a tumor of the cerebellopontile angle, but in most cases the disorder is cryptogenic or autonomic. Treatment consists in paralyzing the nerve with diluted alcohol. In grave cases in which the whole nerve area is affected the nerve must be attacked at the stylomastoid foramen by the anterior or the posterior route. In milder cases with localized spasms excellent results are obtained by paralyzing only the peripheral nerve branches at their issue from the parotid fascia. The picture of the disorder and treatment are illustrated by four cases, and the differential diagnosis is illuminated by one case of cortical origin (Jackson epilepsy) and one of psychogenic hemispasm.

Treatment of Acute Otitis Media with Sulfapyridine.—Hansen reports on the results of the treatment in 127 cases, with 130 nontreated cases as control. The drug seemed to him to have a certain favorable effect, especially in shortening the course in the patients who recover without operative treatment. No positive conclusion could be drawn concerning the patients operated on because of the small number. For the time being he advises against treatment of patients with acute uncomplicated suppuration of the middle ear with sulfapyridine in the practice because of the toxic effects.

Sulfapyridine in Leukemia.—Plum and Poulsen administered sulfapyridine to 2 patients with chronic myeloid leukemia, 2 with acute lymphatic leukemia and 1 with chronic lymphatic leukemia. A transitory improvement in the general condition and the blood picture was seen in the 2 cases of acute lymphatic leukemia.

 Treatment of Eczema. P. Levison.—p. 1148.
 Fracture of Lesser Trochanter: Rare Fracture—How Rare? A. Stefansson.—p. 1148.

Leptospirosis Canicularis with Nephropathy.—The nephritis in Bukh's case was characterized by true uremia, incipient anuria and pronounced impairment of renal function for a long time. The grave nephropathy is ascribed to the canicular infection. Two months after discharge examination of the patient showed complete restoration of the kidney function.

Book Notices

New Facts on Mental Disorders: Study of 89,190 Cases. By Neil A. Dayton, M.D., M.C., Director, Division of Statistics and Director, Division of Mental Deficiency, Massachusetts State Department of Mental Health, 1926.—Cloth. Price, \$4.50. Pp. 486, with illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, Publisher, 1940.

The Massachusetts State Department of Mental Health has had in Dr. Dayton, the author of the present work, a student of statistics of mental diseases who has produced a mass of material previous to this book and in this volume a mass of statistics which is beyond easy assimilation. The modern mental hygiene system of Massachusetts has permitted the collection of statistics on all patients admitted to mental hospitals and other mental institutions between the years 1917 and 1933. There are 56,579 first admissions in this group, and other groups of cases being the total number of cases studied to 89,190. During this period the first World War, prohibition and repeal, and the depression entered into the picture. Most of the material has been tabulated and graphed. There are 110 graphs. The main topics which are considered are age and mental disorders, nativity and alcoholism not only in mental disorders but with regard to other factors such as sex and marital status. Marriage as a factor is reported, and clinical diagnosis is a principal point which is included. The reader going through this volume is amazed at the number of pre-conceived ideas of mental disorders which are exploded by Dr. Dayton's valid statistics. Each of these factors is broken down into as many subgroups as possible; for instance, under marriage the group is divided into rural and urban. There is a religious subgrouping; veterans are compared with nonveterans, the foreign born with native born, the length of time in the United States and other countries. The multiplicity of features leads one to believe that it will be a long time before there is a more thorough study ever made to cover this subject. The ratio of divorces and separations to the total number of marriages and the two combined with regard to education and literacy does not carry with it a comparable table or interpretation. After each table and graph there is a chart discussion. The author goes into the matter at the end of some chapters with a good interpretation of the whole picture. It is interesting to note that the author has a summary at the beginning of the chapter instead of at the end, and this might be a valuable precedent. The book is to be recommended to all those who wish to get a picture of the mental patient who is hospitalized and particularly those *en masse*. It should be full of ammunition for writers on the subject of marriage, alcoholism, sex and mental diseases for some time to come.

A College Textbook of Hygiene. By Dean Franklin Smiley, A.B., M.D., Medical Adviser and Professor of Hygiene in Cornell University, New York, and Adrian Gordon Gould, Ph.B., M.D., Assistant Medical Adviser and Assistant Professor of Hygiene in Cornell University. Third edition. Cloth. Price, \$2.50. Pp. 539, with 135 illustrations. New York: Macmillan Company, 1940.

The first edition of this textbook appeared in February 1928 and a second edition followed in 1934. The present volume is quite up to date and is sufficiently complete to serve as a source of information not only on public health but also on personal health. Indeed, it is aimed primarily as a guide for students as well as a book of instruction in classes. The experiences of the authors as medical adviser and assistant medical adviser in Cornell University give them practical experience on which to base their recommendations. Some of the points which they make have great practical value for every physician. For instance, as a result of their observation of food ordered by students in university cafeterias it was noted that among the chief faults in the selection of food was excessive use of meat, white bread and potatoes, lack of coarse bread, lack of vegetables at the noon meal and a lack of variety of cooked cereals, also poorly cooked and poorly flavored vegetables, too few salads, no variety of fruit at breakfast and a provision of skimmed milk only for drinking purposes. Obviously a little reform in the direction of education regarding diets for students would be a great step toward aiding the national campaign for physical fitness. An especially interesting chapter is the one entitled "You and Your Doctor," which explains why every one should have

a private physician and go to him periodically for examination and advice. One of the best sections here is that on choosing a physician. There is a good statement of the advantages and the disadvantages of the fee for service system and of various technics which have been developed for changing the nature of the practice of medicine. The authors feel that it would appear to be sound procedure to conserve the values that are proving to be inherent in our present scheme of fee for service in medical practice and at the same time to make every effort to remedy its most glaring defects. They offer some suggestions toward improvement. The suggestions are sound. They are based on a reading and an understanding of much of the literature which has appeared on this subject in recent years. This book is supplemented by a good glossary of technical terms and may be heartily recommended as one of the best textbooks available in this field.

Men at Their Worst. By Leo L. Stanley, M.D., Chief Surgeon, California State Prison, San Quentin. With the collaboration of Evelyn Wells. Cloth. Price, \$3. Pp. 322, with 24 illustrations. New York & London: D. Appleton-Century Company, Incorporated, 1940.

For twenty-seven years Dr. Leo L. Stanley has been chief surgeon of the California State Prison at San Quentin. Here he came in contact with many a notorious criminal. He has observed the coming of scientific advancement in the conduct of prisons and has himself experimented widely with plastic surgery, glandular technics and similar problems. In his conclusion he points out that his twenty-seven years of observation have given him no definite conclusions as to prevention of crime through education. In his glandular experimentation he has done over 10,000 testicular implantations and believes that there is a place in the medical management of prisoners through a study of the endocrines. The volume makes an interesting book of reminiscences but is not well organized and does not represent much in the way of a scientific contribution to the questions involved in the care of criminals.

Recent Advances in Sex and Reproductive Physiology. By J. M. Robson, M.D., D.Sc., F.R.S.E. With introduction by Professor F. A. E. Crew, M.D., D.Sc., F.R.S., Director of the Institute of Animal Genetics, Edinburgh. Second edition. Cloth. Price, \$5. Pp. 329, with 62 illustrations. Philadelphia: Blakiston Company, 1940.

This edition indicates the rapid progress made in our understanding of the action and uses of hormones and substances having hormone-like actions related to reproduction. Since 1934, when the first edition appeared, a number of crystalline compounds have been isolated from the various endocrine glands, particularly the gonads and the adrenal cortex, and others with similar properties have been prepared in the laboratory. Our knowledge of the physiologic action of these compounds has thereby been cleared of much confusion resulting from experimentation with crude and relatively inactive extracts of glands. Furthermore, numerous crystalline compounds for therapeutic use have also been made available. Following these developments, innumerable reports have appeared in the past few years on the clinical uses of such substances, studies on their excretion and their metabolism in animals. The literature on these advances has become so vast that the average physician is usually unable to keep abreast of it, and even the specialist has difficulty in digesting the mass of writings. For this reason Robson's monograph is of distinct value. The author has selected a large number of articles from the scientific literature of the world and has evaluated their contents critically and with imagination indicating that the author, who himself has contributed greatly to our knowledge of the endocrines, understands keenly the problems and questions which are most pertinent at the present time. In this manner the reader will be in a position to attain a clear picture of the newer developments in the field. In this book there is discussed systematically the nature of the sex cycle, the histologic changes of the sex organs, the relationship of the various glands to one another, the chemistry, physiology and standardization of the various endocrine principles and the applications of the various preparations to clinical problems. This book is valuable to the physician in giving him an understanding of the principles of therapy and it is also recommended to the physiologist as a means of surveying the recent literature in the field of reproduction.

Methods for Diagnostic Bacteriology: A Complete Guide for the Isolation and Identification of Pathogenic Bacteria for Medical Bacteriology Laboratories. By Isabelle G. Schaub, A.R., Assistant in Bacteriology, Department of Pathology and Bacteriology, The Johns Hopkins University School of Medicine, Baltimore, and M. Kathleen Foley, A.B., Bacteriologist in Charge of the Diagnostic Bacteriological Laboratory of the Medical Clinic, The Johns Hopkins Hospital, Baltimore. Cloth. Price, \$3. Pp. 313. St. Louis: C. V. Mosby Company, 1940.

This book is a manual of methods in diagnostic bacteriology written principally for interns, medical students and student technicians. The book is divided into three parts: The first part is concerned with bacteriologic diagnosis and consists of six chapters, the second part deals with serologic diagnosis and is divided into two chapters, while the third part is concerned with mediums, stains and staining technic, reagents and tests and is composed of three chapters. There are no illustrations, and only one side of the page contains printed matter, leaving the other side for notes. There are no theoretical discussions or explanations, the material being confined to explicit instructions. Many tables are included in which related organisms are differentiated. The book should prove very useful to diagnostic laboratories and to the group for which it was written.

The Organism: A Holistic Approach to Biology Derived from Pathological Data in Man. By Kurt Goldstein, M.D. With a foreword by K. S. Lashley. American Psychology Series. Henry E. Garrett, General Editor. Cloth. Price, \$4. Pp. 533. New York: American Book Company, 1939.

Previous to the present régime in Germany, Kurt Goldstein was considered the leading pathologist in the country. His laboratory in Frankfurt contained a mass of serial sections of the nervous system from the elephant down to the smallest of animals. He had considerable experience in working with traumatic cases in the first World War. After leaving Germany he paused for a short while in the Netherlands, where he wrote the present volume. Then he came to the United States, and his book has been translated into excellent English. In brief, it is a complex but basically sound summary of the general belief about the functioning of the central nervous system. Goldstein believes that the reflexes and other similar concepts of nervous activity cannot be taken out of the theoretical context but that the organism must be thought of as a whole. The point of view is broadly biologic. The clinical material and the research material are included to illustrate points. A number of new concepts are brought out, supported well, such as dedifferentiation, organism as a constant, and life and mind antagonism. It is a splendid, deep and complex study directed toward the psychologist, and undoubtedly of value to the physician or scientist who has to deal with problems of organic neurology.

The Streptococci: Their Descriptions, Classification, and Distribution, with Special Reference to Those in Milk. By William D. Frost, Ph.D., Dr. P.H., and Mildred A. Engelbrecht, Ph.D., Assistant Professor of Bacteriology, University of Alabama, University. Cloth. Price, \$4.25. Pp. 172, with reproductions of 120 photomicrographs. Madison, Wis.: Willdorf Book Company, 1940.

This book contains reports of the investigations which Dr. Frost and his associates have made over a period of many years. The work was supported by the certified milk interests in the Chicago and Milwaukee areas and involves the bacteriologic examination of upward of 25,000 samples of milk drawn directly from the cow's udder. The samples of milk were plated in blood agar and the streptococci present isolated and identified. The methods used in the study are discussed at length in the book. Much space is wasted in the reproduction of photomicrographs of different colonies of streptococci which morphologically are indistinguishable. The book should prove of interest to dairy bacteriologists and to health officers, as well as to veterinarians.

The Virus: Life's Enemy. By Kenneth M. Smith, F.R.S. Cloth. Price, \$2. Pp. 176, with 20 illustrations. New York: Macmillan Company; Cambridge: University Press, 1940.

More and more the viruses are beginning to be recognized as important agents in the causation of disease. Now that smallpox, measles, infantile paralysis, influenza and many other important conditions are being recognized as of this etiology, the public should have an understanding of the nature of viruses at least as good as that which they have of bacteria. These viruses seem to exist midway between the living and the nonliving. They are spread by carriers, both human and insect in type. They are found as infections of plants and lower

animals as well as of man. They vary in their virulence and they seem to be undergoing an evolution which brings them into new diseases such as encephalomyelitis. This volume, prepared primarily for a public audience, will do exceedingly well as a source of information for physicians who have not done much to keep abreast of our advancement in this field. It is written excellently and succinctly. It includes a table of the various important virus diseases and a good index.

The Head and Neck in Roentgen Diagnosis. By Henry K. Pancoast, M.D., Eugene P. Pendergrass, M.D., Professor of Radiology and Director of the Department of Radiology, University of Pennsylvania, Philadelphia, and J. Parsons Schaeffer, M.D., Ph.D., Professor of Anatomy and Director of the Daniel Baugh Institute of Anatomy, Jefferson Medical College, Philadelphia. Cloth. Price, \$12.50. Pp. 976, with 1,251 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1940.

This richly illustrated book deals with the x-ray appearance of the normal head and neck and the x-ray diagnosis of practically all the known anomalies, diseases and injuries of these structures. The book is noteworthy for completeness, clarity and the skill with which the important has been emphasized, the rare, and therefore relatively unimportant, minimized and yet not neglected. Intracranial tumors and the making and interpreting of cerebral pneumograms receive the extensive consideration that their clinical importance requires. The rather large amount of space devoted to the soft tissue structures in the neck is justified by the current interest in this subject and the special qualifications of these authors to speak on it. One looks in vain for sections, chapters or even pages carrying evidence of perfunctoriness, padding, ambiguity, stinginess in indexing, inadequacy of legends or other common faults of medical writing and publishing. Reviewers will find it difficult to employ conventional restraint in describing this altogether spendid and unusual book.

Medical Work on the Knights Hospitallers of Saint John of Jerusalem. By Edgar Erskine Hume, Lieutenant-Colonel, Medical Corps, United States Army. Foreword by His Most Eminent Highness Fro Ludovico Chigi-Albani, Prince Grand Master of the Sovereign Military Order of Malta. Preface by Lieutenant-General Sir Aldo Costellani, K.C.M.G., Count of Chisimale, Professor at the Universities of Rome, London and Louisiana. Reprinted, with additions, from the Bulletin of the Institute of the History of Medicine, May, June and July 1938. Cloth. Price, \$3. Pp. 371, with 131 illustrations. Baltimore: Johns Hopkins Press, 1940.

The Knights of Saint John are a band of Christians who founded a hospital in Jerusalem for the care of the poor and pilgrims. During the Crusades they were driven from the Holy Land and established themselves as an order from Cyprus, Rhodes and Malta. The patron saint of the order was Saint John the Baptist. Among other items in their work is the care of leprosy for the natives of Ethiopia, aid to the wounded in Spain and, indeed, the provision of medical organizations of volunteers in all wars. This record of their contribution is a carefully detailed account illustrated with more than a hundred photographs and supplemented with a good bibliography and an index. For nine centuries this organization has rendered distinguished service in the care of the sick. Colonel Hume's account is a fine contribution to the history of Saint John.

Principles of Surgical Care, Shock and Other Problems. By Alfred Blalock, M.D., Professor of Surgery, Vanderbilt University School of Medicine, Nashville, Tenn. Cloth. Price, \$4.50. Pp. 325, with 13 illustrations. St. Louis: C. V. Mosby Company, 1940.

The problem of making the patient safe for the operation, as Moynihan expressed it, has been yielding slowly to the unremitting assault of many scientists. The ability to evaluate the condition of the patient in laboratory as well as clinical terms has been of great service in reducing surgical morbidity and fatality. This monograph is an extension and amplification of the Beaumont Lectures for 1940. It emphasizes that operation is only part of the treatment of surgical patients. The author has presented well correlated and well digested material. The subjects include the importance of anesthesia and careful surgical technic as well as longer discussions on the circulatory and metabolic systems. The theories of shock and the various associated deficiencies of the circulatory constituents and contents receive ample consideration. Plenty of bibliographic references are included. The book is an enlightening report of the care which a modern surgeon can offer along with his skilful technic and judgment at the operating table.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PERSISTENT PAIN FOLLOWING HERNIA REPAIR

To the Editor:—Four months ago I operated on a 55 year old man for a right direct inguinal hernia. After ligating and amputating the sac, I sutured the conjoined tendon to Poupart's ligament along with the medial flap of the external oblique fascia under the cord and imbricated the lateral flap over the cord. He was in bed for two weeks, and shortly thereafter he began to complain of pain, usually sharp and sometimes radiating to the inner aspect of the thigh. At no time was there induration of the cord or swelling of the testis. After I injected procaine hydrochloride solution in the region of the cord just lateral to the pubic tubercle, this point being the distal end of the incisional scar, the pain and tenderness disappeared, only to reappear after the anesthesia wore off. Believing that the nerve which accompanies the spermatic cord might be caught in a ring of scar tissue, I reopened the wound and dissected free the cord, the nerve and its branches at the distal end of the old herniorrhaphy scar. This failed to relieve his symptoms. There is no evidence of recurrence of the hernia. What is the cause of the pain and how can it be remedied?

M.D., Michigan.

ANSWER.—The report of this case seems to indicate a scar or ligature compression of a peripheral sensory nerve, despite the fact that at the second operation a nerve was seen to be free. In this region one deals with two nerves, the iliohypogastric and the ilioinguinal. Callander (Callander, C. L.: *Surgical Anatomy*, Philadelphia, W. B. Saunders Company, 1934, p. 407) said, "The iliohypogastric nerve runs forward in the abdominal wall near the superior margin of the iliac crest, and there divides into hypogastric iliac branches. The hypogastric branch continues forward to a point about 2.5 cm. above the subcutaneous inguinal ring, where it pierces the aponeurosis of the external oblique and is distributed to the skin of the hypogastric region. The iliac branch crosses the iliac crest and is distributed to the skin of the forepart of the gluteal region. The ilioinguinal nerve enters the region at a somewhat lower level than the iliohypogastric and, after crossing part of the iliac fossa, enters the inguinal canal. It runs anteriorly beneath the aponeurosis of the internal oblique immediately above the inguinal ligament and emerges from the subcutaneous inguinal ring." A case similar to this is known in which the man walked with a list to the side because of the pain and had been given orthopedic treatment. He was not cured until the nerve was dissected free of the scar tissue. In the case referred to in the query one would certainly think that further exploration of the wound is desirable until both ilioinguinal and iliohypogastric nerves are identified and traced to their extreme ends. If it is not possible to free the distal branches of the affected nerve, it would probably be better to section it high and possibly inject it with alcohol.

EXPOSURE TO SYPHILIS

To the Editor:—A man with a fresh chancre diagnosed by dark field had intercourse a week ago without prophylaxis or contraceptives being used. What is the best procedure now in reference to the woman? Should treatment be instituted immediately with her and how much, or should her vaginal tract be inspected daily until the appearance of the expected chancre and then treatment started? I realize that starting treatment without definite evidence of infection is forever labeling her as syphilitic whether she would have been or not. Presumably she now has a negative Wassermann reaction, which test has been taken.

M.D., New York.

ANSWER.—The proper procedure in the case outlined depends, of course, on the probability of the woman having become infected with syphilis. Were she certain to become infected one could make a good case for the immediate institution of antisyphilitic treatment, arguing that since treatment results are known to be best in the seronegative primary stage they should be even better in the seronegative stage before the primary lesion has developed. Under the circumstances detailed, however, infection of the woman is by no means certain. This would be true even if the penile lesion which was found to be darkfield positive had been present at the time of intercourse; one gathers, however, that the penile sore developed after the last intercourse with the woman, in which case her chances of escaping infection are excellent. She should be

carefully observed both clinically and serologically; at the first examination the cervix should be inspected through a speculum, in addition to a close scrutiny of skin, mucosal surfaces and genitalia. The procedure from this point on would depend somewhat on the time at which the patient came under observation, since the desirable maneuvers are related to the date of her exposure.

From this date she should have a serologic test for syphilis done at two, four, five, six, seven, eight, nine, ten and twelve weeks, assuming of course that it continues to give negative results and finally, before being discharged from observation, a final test four months after exposure. If at all practical, a complete inspection including a speculum examination is highly desirable but is urgently necessary only in the first few weeks when there is the opportunity to make the diagnosis of syphilis in the seronegative stage, in case she has acquired the disease.

This is the setup for the use of the so-called prophylactic dose of arsphenamine, which is a dangerous and fortunately outmoded procedure. Actually to administer any antisyphilitic treatment to this woman would, for safety, necessitate the completion of the entire schedule of treatment for seronegative primary syphilis, just as though that diagnosis had been made.

ADDICTION TO PAREGORIC

To the Editor:—Seven years ago a man who is now 33 years old was in an automobile accident and, as a result, afterward suffered from frequent headaches. It was because of the severity of these headaches that he began to take paregoric. He had also a 4 plus Wassermann and has taken treatments for about ten weeks. In the beginning he started with 2 ounces of paregoric each day, gradually increasing the amount until he was taking a pint a day. Two years ago he started to inject the paregoric by boiling the alcohol off and then straining it through cotton, using an eye dropper and a needle for the injection. By this method he has ruined every vein in his arms and legs. He has gone to many different drug stores and is now unable to obtain paregoric from any one of them. He says he can get along fairly well with 4 oz. (120 cc.) daily, that is, 1 ounce (30 cc.) per dose, but is unable to obtain even that amount. In order to fight the habit he has tried to become a drunkard, but alcohol alone has had little effect. He has also tried pentobarbital sodium, having taken it intravenously, but after ten minutes' sleep he wakes feeling worse. At present he can walk only about 20 to 30 feet and is then forced to rest because of shortness of breath. This man is anxious to overcome the habit. He would like to take antisyphilitic treatments.

M.D., West Virginia.

ANSWER.—The underlying causes of narcotic addiction are in the personalities of the addicts. No person is immune to opiate addiction. Morphine administered to any hundred persons will in time produce abstinence symptoms and make 100 addicts. However, there are two major types of personalities, the potential and the nonpotential narcotic addict. There are many persons who are unsuspecting potential narcotic addicts, who get along well until narcotic drugs come into their lives. The ones who do not succumb are not always the stronger willed; but the excessive indulgence holds no appeal to them, and often they get more pain than pleasure from it, so the experience is not repeated. One should avoid repeating the dose of opiate when great relief is given or more than an anodyne effect is secured, especially in neurotic patients. More than 75 per cent of the addicts seen today who do not belong to the vicious type are made up of the inadequate personalities who are unwilling or think they are unable to stand physical or mental stress without the relief of narcotism. The patient in question is definitely a potential addict who either is of the vicious type or who has been associating with such people to the extent that he has adopted their methods. A normal accidental addict does not inject paregoric, use an eye dropper and a needle and resort to intravenous injections to obtain a greater "kick," ruining every vein in his arms and legs and using greater amounts than are necessary.

The fact that the patient does not care for pentobarbital sodium or alcohol means that he is unwilling to accept a weaker substitute for his accustomed opiate. Syphilis does not need narcotic relief. This patient can be successfully denarcotized at any reputable institution where narcotic patients are accepted; those in charge will ascertain whether he has a really incurable disease that necessitates narcotics, and if not they can, after disintoxication treatment, attempt to rehabilitate him if he has the financial means. However, from the history the prognosis is unfavorable. If the patient's means are limited an institution nearly similar to the Narcotic Farm at Lexington, Ky., offers the best chance of a favorable outcome.

ADHESIVE FOR CIGARET PAPERS

To the Editor:—During a discussion of cigarettes and their composition one mentioned the fact that the paste which glues the cigaret paper together might be harmful. Could you inform me as to the composition of the substance used to paste the cigaret paper together and if it is at all harmful?

B. B. Favuzza, M.D., Franklin Square, N. Y.

ANSWER.—Although some types of cigarettes, such as the hollow stemmed East European varieties, are made without paste, by crimping the paper along the edge, and others may use dextrin, starch or similar vegetable pastes, by far the greater number, including almost all of the popular American blends, are made with the use of an adhesive made of casein, the protein obtained from milk. The products of combustion or destructive distillation of this protein include ammonia and other nitrogenous substances, which may be irritating in high concentration. The extremely minute amount of the material used in the production of cigarettes, however, compared with the amount of tobacco and paper present, makes it impossible to detect any differences in the composition of the smoke due to the presence or absence of the adhesive. There is no evidence therefore and, in fact, little possibility that the substance used to paste the cigaret paper together is at all harmful.

FACE MASKING IN NEWBORN NURSERIES

To the Editor:—Will you please make a statement as to the status of "nurse masking" in the nursery? How generally is it practiced? Does the Chicago Board of Health require it in Chicago hospitals? Would a hospital not employing such masking be legally liable for contagious spread through the respiratory system affecting its nursery patients?

E. D. Huntington, M.D., Chicago.

ANSWER.—The rules and regulations of the Chicago Board of Health for maternity hospitals require that nurses, physicians and all others entering the newborn nursery wear a suitable face mask all year, except during the summer months; these rules are strictly adhered to by Chicago hospitals. During the summer months, the wearing of face masks by the nursing and other personnel is optional.

The fixing of legal responsibility, in instances in which infection of the respiratory tract spreads through the nursery, would require thorough investigation and often would be impossible to establish. Obviously, if any of the personnel are suffering from such an infection they should not be permitted to work in the nursery. If they do not have an active infection of the respiratory tract it would be difficult to demonstrate the failure to wear a face mask as responsible for an outbreak of respiratory disease.

ABDOMINAL DISTENTION IN DIABETIC GIRL

To the Editor:—A diabetic girl aged 14 years was hospitalized four weeks ago and the blood sugar was brought from 400 mg. to 120 mg. by use of a 1,650 calory diet made up of protein 80 Gm., fat 90 Gm., carbohydrate 135 Gm. and insulin. She was discharged from the hospital after two weeks on this diet and insulin (regular 40 units to the cubic centimeter), 35 units before breakfast, 20 units before lunch and 30 units before dinner. Two days later she complained for the first time of abdominal distention, which was extreme and caused moderate embarrassment at breathing. The gain in weight was 13 pounds (6 Kg.) in two weeks. Except for this condition she felt much better than previously and her appearance was much improved. There was no complaint of distention while she was in the hospital bed. Several days later a complete gastrointestinal examination was done and was negative. Chest x-ray films showed slight hypertrophy of the heart. The pulse ranges from 104 to 114 per minute and is regular in rate. The heart sounds are normal and the rate is regular. The lungs are normal to physical and x-ray examination. Abdominal examination reveals a generalized and extreme distention which is tympanitic in character; there are no masses or tenderness. The bowels are regular, and spontaneous daily movement occurs. Urine examination is negative except for sugar, which ranges from 1 plus to 2 plus with occasional negative tests in the morning. There is no evidence of edema. She complained once of dimness of vision but this cleared up. The thyroid is normal in size. Urinary output and intake balance normally. In the morning there is little or no distention on arising but it gradually increases during the day to a maximum in the evening. At the night meal she feels "too full to eat," although she does eat the prescribed diet. The diagnosis of diabetes mellitus was first made by another doctor six months ago and insulin was taken in approximately the same dosage as at present for three months. During the period insulin was taken the same distention occurred and persisted in spite of all treatment until insulin was stopped. There was no distention present during the period when no insulin was taken. I have exhausted all possibilities that I know of in trying to determine the cause of this condition. I have been unable to find a parallel case in the medical records indicating any relation between large doses of insulin and abdominal distention. Any help that you might give me would be greatly appreciated.

M.D., New York.

ANSWER.—Several possibilities suggest themselves as the cause for the unusual abdominal distention:

1. The condition is reminiscent of that seen when diabetic children received bulky diets, especially those containing bran along with large amounts of leafy green vegetables. Is it pos-

sible that at home the patient takes additional food, particularly in the form of broth or between-meal lunches? If she was using certain diabetic candies and diabetic cookies she might be receiving a good deal of bran or agar agar.

2. Does the patient swallow air during rapid eating?

3. Can the condition be related to the rapid gain of weight, 13 pounds in two weeks, incident to bringing the diabetic condition under control? This implies retention of water in a body previously dehydrated and, since there is no peripheral edema ("insulin edema"), one wonders whether there may not be some fluid in the abdomen.

4. It is difficult to believe that the distention and attendant gastrointestinal symptoms represent an unusual type of allergic response to insulin, particularly since no other manifestations of hypersensitivity are described.

5. In juvenile patients with severe diabetes who are maintained entirely on regular insulin (without protamine zinc insulin) it is not uncommon to have marked enlargement of the liver with abdominal distention, which at times may be so great as to give rise to a "pot-belly" habitus. The liver may be difficult to feel on physical examination but should be evident by x-ray examination. In the case under discussion it is possible that this manifestation of disturbed metabolism became evident only when there was retention of water in the liver following institution of treatment with insulin.

6. The possibility should be kept in mind that the abdominal distention is due to some cause entirely apart from diabetes, such as a megacolon, abdominal tuberculosis or vitamin deficiency. Why should the heart show "slight hypertrophy" and why is there tachycardia?

Extensive studies have already been carried out. One can suggest only that the patient be kept under close watch so that other observations as regards both diabetic and nondiabetic complications can be made. It is likely that shifting the patient to a combination of protamine zinc insulin and regular insulin, both types given daily before breakfast, would permit even better control of the diabetic condition.

DIGITALIS FOLLOWING STROPHANTHIN

To the Editor:—I am of course aware of the precautions necessary concerning the use of strophanthin when a patient has been receiving digitalis, but what I have been unable to find is information concerning the use of digitalis when a patient is receiving strophanthin. Is it possible merely to substitute a maintenance dose of digitalis when the strophanthin is discontinued or is digitalization necessary to the same extent as with a patient who has received no prior medication?

M.D., Iowa.

ANSWER.—Since strophanthin is excreted more rapidly than digitalis, its cumulative effect is comparatively small. It is advisable, therefore, to start with higher than just maintenance doses of digitalis when therapy shifts from strophanthin given intravenously to digitalis given by mouth. However, the dose of digitalis chosen depends on the intensity of the previous treatment with strophanthin and the response to it. After a single dose of strophanthin, digitalization will be necessary to the same extent as when a patient has received no prior medication. When daily injections of strophanthin are given a high degree of "digitalization" can be obtained, and for patients receiving these it may be sufficient to continue with ordinary maintenance doses of digitalis administered orally. If intoxication occurs after intravenous strophanthin therapy, an interval of a few days should be allowed to elapse until the toxic manifestations have disappeared, just as is done after excessive digitalization, after which maintenance doses of digitalis can be resumed.

MICROSCOPIC DIAGNOSIS OF MALIGNANT TISSUE

To the Editor:—What are the principles of the microscopic diagnosis of cancer? Which is more important, the morphology of the cell or the architecture of the tissue? Why do skilled pathologists so frequently disagree in their diagnosis of tumor? In the textbooks of pathology which I have consulted but little information on this important subject can be obtained.

M.D., Kentucky.

ANSWER.—The morphologic signs of malignant disease are variations in size and shape of cells, hyperchromatism of nuclei, and excessive mitotic activity. When these microscopic features occur among cells which still remain within normal boundaries the lesion is designated as precancerous or potentially cancerous. The criterion of fully established malignant disease is when cells having these morphologic appearances have transgressed their normal boundaries. Skilled pathologists disagree in their diagnoses of tumors because the microscope has definite limitations and because it is difficult to estimate the biologic character of a tumor from its morphologic appearance.

THE PROPHYLACTIC USE OF SULFANILAMIDE

IN PATIENTS SUSCEPTIBLE TO RHEUMATIC FEVER

CAROLINE BEDELL THOMAS, M.D.

RICHARD FRANCE, M.D.

AND

FRANJO REICHSMAN, M.D.

BALTIMORE

This is the report of a four year study to determine whether sulfanilamide (para - amino - benzene - sulfonamide) administered prophylactically prevents recurrences of acute rheumatic fever. A preliminary description of the first two years of our work appeared in January 1939.¹

As Coburn² and others have shown, beta hemolytic streptococcus infections usually precede episodes of rheumatic fever, and the antistreptolysin titer of the patient's blood is elevated during the attack.³ While the beta hemolytic streptococcus is not considered to be the direct and sole cause of rheumatic fever, its close association with periods of rheumatic activity makes it seem probable that the organism plays a significant role in initiating the disease process. If the factor of infection with the beta hemolytic streptococcus could be removed or sufficiently attenuated, it is possible that the active rheumatic state might not reappear in a susceptible person.

The Tréfouëls, Nitti and Bovet⁴ in 1935 and Buttle, Gray and Stephenson⁵ in 1936 reported that sulfanilamide exerted a protective effect in experimentally induced beta hemolytic streptococcus infections in mice. They injected living organisms intraperitoneally into mice and noted that animals fed sulfanilamide immediately afterward survived longer than unprotected control mice. Coburn and Moore⁶ in 1939 described

experiments in which guinea pigs were completely protected both from spontaneous and induced cervical adenitis of beta hemolytic streptococcus origin by the prophylactic administration of sulfanilamide.

The drug has been used prophylactically in human beings in attempts to control puerperal infections⁷ and epidemics of streptococcal tonsillitis⁸ and scarlet fever⁹ with varying degrees of success. Administered during measles or whooping cough, it apparently reduces the incidence of complications, especially bronchopneumonia.¹⁰ It is also being used routinely in the Johns Hopkins Hospital and elsewhere in the prophylaxis of infections following compound fractures and extensive lacerations.

Several articles have been published on the effect of sulfanilamide administered during the course of acute rheumatic fever and chorea, including those by Swift, Moen and Hirst¹¹ and Massell and Jones.¹² These authors and others agreed that clearcut beneficial results from such treatment were absent and that toxic symptoms, notably increased fever, tachycardia and rash, were almost universal. In general, the period of treatment was short; Swift and his associates gave moderate doses to 8 patients over a period of from three to seven days. Massell and Jones, using a larger dose, maintained the therapy from a few days to two months. They did not state the number of patients treated for periods longer than two weeks. On the basis of these studies, it has been generally accepted that the use of sulfanilamide is contraindicated in acute rheumatic fever. The fact that sulfanilamide does not behave in such a manner in other diseases suggests that further study of this apparently toxic reaction might throw light on the pathogenesis of rheumatic fever.

At the same time that our original report appeared, Coburn and Moore⁶ reported studies on the prophylactic use of sulfanilamide in several groups of rheumatic children. Administered to rheumatic subjects after the onset of streptococcal pharyngeal infections, the drug did not prevent rheumatic recrudescences. However, seventy-nine out of eighty children to whom sulfanilamide was administered continuously throughout the winter escaped hemolytic streptococcal infection and signs of rheumatic activity. In this, Coburn's and

Moore's findings and ours were in virtual agreement. Unfortunately, while their study included twenty-five children living in their normal home environment, the rest were segregated from infection in a convalescent home, and adequate control studies were not made.

The present study has been kept on the simplest possible basis: Small daily doses of sulfanilamide were administered over a period of months to adolescents and young adults who had suffered from one or more attacks of acute rheumatic fever, the last one occurring within three years of their inclusion in this study. Other patients with similar history were observed as controls each winter. With minor exceptions, we adhered to a uniform dose throughout chosen with the idea of giving a dose definitely smaller than a therapeutic one yet large enough to maintain an ascertainable level of sulf-

discharge. A few patients had been observed during their acute illnesses in the wards of other hospitals¹⁴ and through the kind cooperation of the staffs of those hospitals were transferred directly to the cardiac clinic. The patients were chiefly drawn from the middle and laboring classes of society; only a few were destitute.

In all, 90 patients were followed in the treated and control groups combined (charts 1, 2, 3 and 4). Twenty-one patients were observed throughout the four year period; 21 were followed for three years, 24 for two years and 17 for one year. In addition, 4 died (2 during the third and 2 during the fourth year of observation, and 3 patients were lost sight of, 1 during the second and 2 during the third year of observation.

The distribution of cases between the treated and control groups was not made entirely by lot. Each

anilamide in the blood. Sulfanilamide was the only drug used throughout the four year study; we made no attempt to evaluate any of the newer sulfonamide derivatives such as sulfapyridine. In general, treated patients were started on sulfanilamide during October and November and were given the drug continuously throughout the winter and spring, the drug being stopped in June. The sedimentation rate was determined by the method of Wintrobe¹³ at every visit of both treated and control patients. By this technic, the upper limit of normal for the corrected sedimentation rate at the end of an hour is 10 mm. for both males and females.

SELECTION OF PATIENTS

Almost all of the patients had been observed in the medical wards of the Johns Hopkins Hospital during one or more attacks of acute rheumatic fever and were transferred to the cardiac clinic to be followed after

year except the first¹ some of the patients were placed in the treated and some in the control group by the alternation of patients who were similar in age, length of history of rheumatic fever and degree of cardiac involvement. After one year of treatment half were shifted to the control group and half kept in the treated group by the same process. However, several additional factors operated to take patients out of the treated into the control group:

1. Some patients were entirely willing to take the treatment but were not able to attend the cardiac clinic for observation regularly enough. Generally, such patients were employed¹⁵ or lived at a considerable distance.

2. Some patients did not want to be treated or did not want to attend the cardiac clinic frequently even though they were able to do so. These were usually young people who felt perfectly well and who refused to believe that there was any-

14. Baltimore City Hospital (N. P.), Sinai Hospital, (M. D., H. E., N. S., E. Z.), Union Memorial Hospital (M. H., G. H., G. N.).

15. On the other hand, many employed patients came in frequently and were in the treated group.

13. Wintrobe, M. M.: The Erythrocyte Sedimentation Test, Internat. Clin. 2: 34 (June) 1936.

thing serious the matter with them or any imminent danger of recurrent illness. They were not necessarily unintelligent or unhygienic in other ways.

3. Some patients were selected by lot to take sulfanilamide and agreed to do so but repeatedly forgot to take the drug, lapsed in frequent attendance at the clinic and when they did come showed no detectable sulfanilamide in the blood. After several attempts to rally them into better cooperation they were transferred to the control group.

Two patients were transferred from the treated to the control group on account of mild symptoms of toxicity from sulfanilamide which recurred when repeated attempts to administer the drug were made.

The patients in groups 3 and 4 received only a small amount of sulfanilamide each, taken in a discontinuous fashion over a period of weeks. They were, therefore, never included in the treated group but were placed permanently in the control group. Sulfanilamide therapy was never again attempted in subsequent years for such patients.

To offset these patients who through necessity were shifted into the control group still other new ones were added to the treated group. It cannot therefore be said that the treated and control groups were identical, but efforts were constantly made to keep them as nearly comparable as possible. For instance, while factors 1, 2 and 4 prevented certain patients from being treated, their diet, housing, intelligence, general hygiene and cardiac lesions were not essentially different from those in the treated group. On the other hand, some of the uncooperative ones (group 2, previously mentioned) and many of those who lapsed during therapy were definitely inferior to those in the treated group. These factors have been analyzed and summarized in table 1. As will be seen later (table 6), however, relapses in control patients occurred as often among the well endowed as among the poorly endowed. Finally, 32 of the patients were in the treated group part of the time and in the control group part of the time, so that here the equivalence was exact.

The patients varied in age from 7 to 37 years at the time of entering the study. The ages as listed in charts 1, 2, 3 and 4 are referred to the date of entry, indicated by the heavy vertical line. By far the greater number of patients were between the ages of 14 and 26. The age distribution was similar in the treated and control groups (table 2). Since patients under 14 were not available in the Department of Medicine, we were able to observe only five children under that age, four of whom were generously transferred to our care from other hospitals.

HISTORY OF RHEUMATIC FEVER

Every patient had had one or more "major rheumatic episodes," the last one occurring within three years of entering the study. A major episode is defined as one in which the patient is ill enough to be confined to bed at home for at least a week or to be hospitalized and in which fever, polyarthritis, active carditis, chorea or other signs are unequivocal. Undoubted chorea is considered a major episode only in the event the patient affected has suffered from other forms of rheumatic fever as well. All major episodes occurring before or after entering the study are indicated in the charts by black blocks. No attempt has been made to illustrate the severity or duration of the attack or the months in which the attack occurred, except to show, during the period of study, whether the attack came before, during or after the period of prophylactic treatment.

A minor episode signifies a definite but less incapacitating form of rheumatic fever, such as transiently painful, swollen joints or mild choreiform movements. A questionable episode includes any illness in which the diagnosis of rheumatic fever is in doubt, as well as such isolated symptoms as epistaxis, sore throat, arthralgia or precordial pain in a rheumatic person. The minor and questionable episodes occurring during years before entering the study are often poorly or incorrectly remembered, and so no attempt has been made to chart them. Those occurring during the period of study, therefore, are not charted but are described later in this paper.

Without discussing in detail the cardiac status of the 90 patients studied, it may be briefly stated that 62 patients, or 68.9 per cent, had definite chronic rheumatic endocarditis with involvement of one or more of the valves of the heart; 9 patients, or 10 per cent, had questionable valvular disease, and 19, or 21.1 per cent, had no definite signs of endocarditis and were classified as patients with potential heart disease. Thirty patients (33.3 per cent) had definite cardiac enlargement, 12 patients (13.3 per cent) had hearts that were questionably enlarged and 48 patients (53.4 per cent) had hearts of normal size. Finally, the functional cardiac capacity was definitely impaired in only four instances (4.4 per

TABLE 2.—Age Distribution of Treated and Control Patients

cent) and questionably impaired in seven others (7.8 per cent); by far the greatest number of patients (79, or 87.7 per cent) were able to carry on ordinary physical activity without any discomfort whatsoever. The distribution of these factors among the treated and control groups is analyzed in table 1.

ADMINISTRATION OF SULFANILAMIDE

Dosage.—During the season of 1936-1937, the treated group of patients received 0.9 Gm. (actually 15 grains) of sulfanilamide daily, divided into three doses. In the subsequent three seasons of 1937-1938, 1938-1939 and 1939-1940, 1.2 Gm. (20 grains) was administered daily, divided into two doses taken twelve hours apart.¹⁶ While theoretically it would be preferable to divide the medication into three or four doses distributed throughout the day, the increased likelihood of doses being skipped made it seem wise to reduce the routine to the simplest possible form. Each patient's schedule of medication was arranged with him with especial regard to convenience. The morning dose was usually taken on first arising or just before breakfast, the second dose exactly twelve hours later.

In the effort to protect patients during the winter and spring when rheumatic recrudescences are most frequent, the season of prophylactic treatment was begun during October and November and continued until June. Since a small number of patients are seen at each

16. The patients under 14 years of age were given 0.9 Gm. daily; in 1 (M. H.), the dose was later increased to 1.2 Gm. In several patients who excreted sulfanilamide with great rapidity the dose was raised to 1.8 Gm. a day.

biweekly session of the cardiac clinic it took several weeks for the whole group to start and stop the drug. With two exceptions,¹⁷ no patient was given sulfanilamide during the months of July, August or September. The average length of a season of prophylactic therapy was eight months, the season varying from seven to nine months. In the last two years 5 patients began late and took sulfanilamide for shorter periods, and this is indicated in chart 2. The cross-hatched areas in charts 1 and 2 indicate the seasons when prophylactic treatment was administered to each person.

FREQUENCY OF VISITS AND CONTINUITY OF TREATMENT

As a rule the patients receiving sulfanilamide were seen in the cardiac clinic at three week intervals throughout the period of treatment. Actually most of

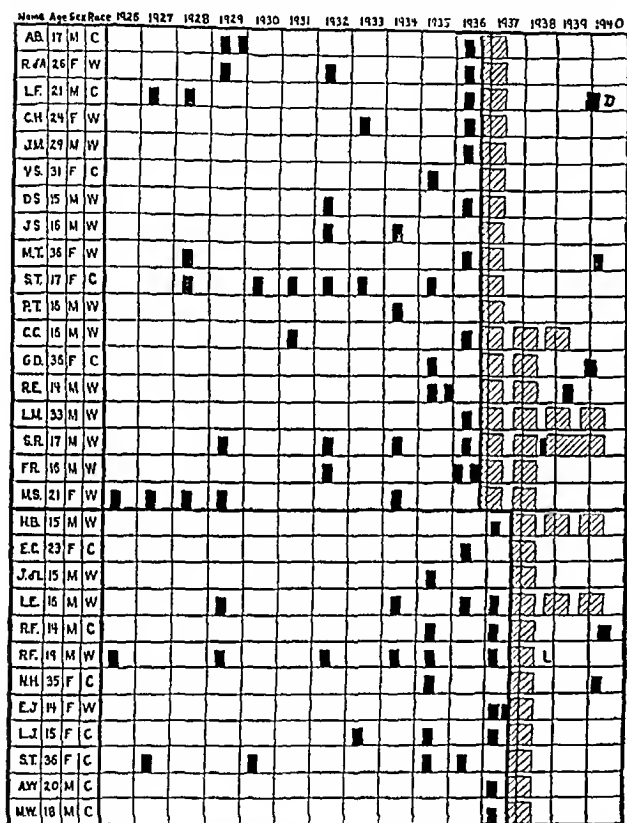

Chart 1.—Major episodes of acute rheumatic fever in patients taking sulfanilamide prophylactically who entered the study in 1936 and 1937. The heavy vertical lines indicate the date of entering the study. The heavy horizontal line divides the groups entering the study in successive years. Each black block represents a major rheumatic episode. Cross-hatched areas indicate periods of prophylactic sulfanilamide therapy. D, died; L, lost.

them were seen more frequently when the drug was first given; later, when everything was running smoothly, the interval was sometimes lengthened a little. Some of the patients in the control group were seen as frequently as those in the treated group; many were seen less frequently. Some were checked at half-yearly or yearly intervals. In order to follow every patient up to July 1, 1940, the date this study closed, a few control patients who could not be brought into the cardiac clinic were questioned by letter as to occurrence of rheumatic fever or other illness. All but 1¹⁸ replied that they had been perfectly well.

¹⁷ These 2 patients, S. R. and C. d'L., had had attacks of rheumatic fever during the summer months of the previous year.

¹⁸ M. R.: See later in article under "questionable episodes."

CONCENTRATION OF SULFANILAMIDE IN THE BLOOD

Determinations of the concentration of sulfanilamide in the venous blood were begun in April 1937 and were subsequently made at each visit during the periods of treatment. The method of Marshall¹⁹ was used. When 0.9 Gm. of the drug was taken daily in three divided doses the concentration of the drug in the blood fluctuated between 1.0 and 3.0 mg. per hundred cubic centimeters. On 1.2 Gm. a day divided into two doses, patients were usually found to have a blood sulfanilamide level varying between 1.8 and 3.0 mg. per hundred cubic centimeters during the morning, one and a half to five and a half hours after the morning dose. The level at times rose even higher and occasionally fell low. Twelve hours after the last dose had been taken the blood sulfanilamide level was below 1.0 mg. per hundred cubic centimeters, and twenty-four hours after a dose only a trace of sulfanilamide was found. There was no tendency toward accumulation of the drug when administered over a long period of time.

TOXIC EFFECTS

Most of the patients took the drug without the slightest discomfort. The toxic symptoms which follow larger therapeutic doses were rarely if ever observed on the small daily dose administered during this study. We have never encountered cyanosis, anemia, granulocytopenia, acidosis, severe dermatitis or febrile reactions. Despite the experience of Coburn and Moore,⁶ there was no tendency toward loss of weight or inability to gain weight among our patients. A few patients complained of vertigo or drowsiness during the first few days of drug therapy but subsequently felt perfectly normal. One rather overconcerned boy stated that he "could not think as well," but he continued the drug during two seasons and performed his clerical work satisfactorily.

During the first two seasons only a few extremely slight reactions were encountered; 3 patients complained of transient vertigo, and 2 noted mild erythematous eruptions. None of the patients stopped the drug permanently on account of toxic symptoms. During the seasons of 1938-1939 and 1939-1940, 2 patients were transferred from the treated to the control groups because of mild reactions:

T. d'R., an Italian boy, whose mother and father were subject to urticaria and hay fever respectively, complained of urticaria which first appeared four weeks after he started sulfanilamide and which disappeared and reappeared when the drug was stopped and then resumed. Later he was again started on sulfanilamide in doses of 0.15 Gm. a day. He complained of drowsiness, fatigue and nausea after taking the drug three days and refused to continue to take it.

N. S., a Jewish boy of 7 years, was started on 0.9 Gm. of sulfanilamide daily when he was clinically and symptomatically well, with normal temperature and sedimentation rate. The white blood cell count, however, was recorded as 19,150, with 50 per cent polymorphonuclears and 5 per cent juvenile neutrophils. This count was not checked. Three days later a mild infection of the upper part of the respiratory tract developed in him, and his mother thought he looked red and hot. When seen a week after starting the drug he complained of fatigue, his throat was slightly injected, his temperature was 99.4 F. and his sedimentation rate normal. The blood sulfanilamide level was 2.0 mg. per hundred cubic centimeters. His white blood cell count was now 4,300, with 17 per cent juvenile and 28 per cent adult polymorphonuclears—a total of 45 per cent. On account of the leukopenia the drug was stopped. During the next two visits his white cell count rose to 9,500

¹⁹ Marshall, E. K., Jr.: Determination of Sulfanilamide in Blood and Urine, *Proc. Soc. Exper. Biol. & Med.* 36: 422 (April) 1937.

and then to 11,550, with 4 per cent and 11 per cent juvenile forms and 61 per cent and 37 per cent adult neutrophils respectively. He was again started on sulfanilamide; 0.3 Gm. was administered one evening, and 0.3 Gm., the next morning. When he awoke that morning his face was "very red," and the redness persisted, although he had no complaints, so he was brought to the hospital. The boy's cheeks were crimson, with marked circumoral pallor. There was a slight erythema over the flexor surfaces, not accentuated in the axillary folds. He seemed tired and "toxic." There was no fever, no strawberry tongue or injection of the pharynx. The leukocyte count was 14,150. The drug was stopped, and his parents observed that the redness of the face soon disappeared. Seen two days later he seemed normal; the leukocyte count was 6,700, with 3 per cent juvenile and 38 per cent adult neutrophils.

On account of the drop in the total leukocyte count without granulocytopenia on two occasions, as well as the erythema and the feeling of lassitude, the drug was permanently stopped in this instance.

Other toxic reactions, which did not necessitate permanent stopping of the drug, were as follows:

In D. R. an itching rash developed over the dorsal surfaces of her extremities, associated with erythema, nine days after starting sulfanilamide. The rash disappeared two days after the drug was stopped. Two weeks later the patient started to take 0.6 Gm. a day, and in twenty-three days she noted an itching rash on her wrists which again disappeared promptly on discontinuing the pills. Three days later she was started once more on the drug, which was increased rapidly to the full dose without untoward effects, and continued for the remainder of the season.

G. H., aged 9, may have had slight drowsiness and fatigability during the first eighteen days of the administration of 0.9 Gm. of the drug daily, and his mother noted a little rash on the calves of his legs but nowhere else. These questionable effects were not noticed during subsequent months of sulfanilamide therapy.

Although the hemoglobin, volume of packed red cells and sedimentation rate were carefully followed throughout the four year study, frequent determinations of the white blood cell total and differential count were not made until the season of 1939-1940. Of 14 patients receiving sulfanilamide for the first time in 1939-1940, 8 had normal white blood cell counts throughout the period of treatment. Five showed a drop in total white blood cell count to levels between 4,000 and 5,000 without granulopenia. In two instances the leukopenia was present on one visit to the clinic only, eleven days and twelve weeks after starting sulfanilamide. In 2 other cases the leukopenia, first noted five and a half weeks and twelve weeks respectively after beginning sulfanilamide, persisted for a three month period. These 4 patients continued and completed their sulfanilamide courses without untoward effects. The fifth patient, N. S., is described in detail earlier in this section. One patient (whose total leukocyte count was 4,800 when the drug was started) showed a drop to 2,950 leukocytes in three weeks and to 2,600 with 60 per cent granulocytes four days later. Sulfanilamide was stopped. The leukocyte count rose to 5,500 in two weeks. Sulfanilamide was again started and continued for the next six months; the leukocyte count fluctuated between 4,300 and 5,400 throughout this period.

Finally, 1 patient (G. C.) who took sulfanilamide in both 1938-1939 and 1939-1940 and whose usual leukocyte count fluctuated between 4,400 and 6,500 began the drug late in October 1939 on a day when her leukocyte count was 4,500. The white blood cell count remained between 4,500 and 4,900 until the end of January 1940. Early in February she had influenza and from then until the last of April her leukocyte

count lay between 3,150 and 3,750, returning to more than 5,000 thereafter. The drug was not stopped during the period of leukopenia.

Thus we observed no alarming reactions from the administration of sulfanilamide during our four years of study, nor were the patients disturbed by symptoms more distressing than drowsiness or itching. Some drop in total leukocyte count over a period of days or weeks was not uncommon, but the phenomenon was self limited and was never accompanied by granulopenia.

EFFECT OF TREATMENT

Beta Hemolytic Streptococcus Infections.—None of the patients receiving sulfanilamide prophylactically suffered from acute beta hemolytic streptococcus infection during the period of treatment. Among the control patients, A. M. was hospitalized in April 1937, with an acute sore throat; pharyngeal culture showed 98 per cent beta hemolytic streptococci. In October 1938, E. J. had an infection of the leg from which an almost pure culture of beta hemolytic streptococci was obtained.

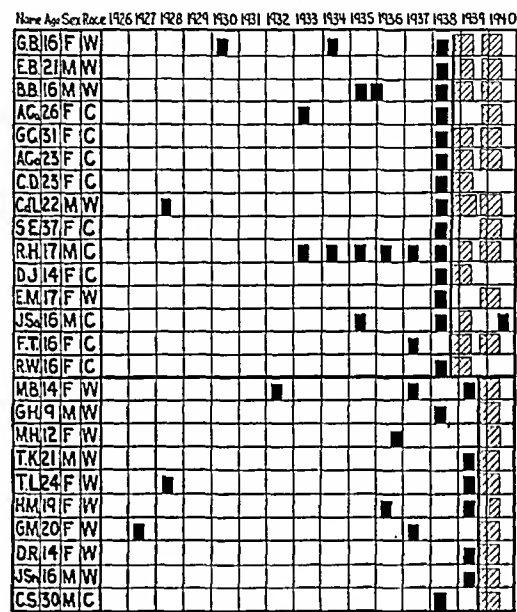

Chart 2.—Major episodes of acute rheumatic fever in patients taking sulfanilamide prophylactically who entered the study in 1938 and 1939. The symbols are as given in chart 1.

Pharyngeal cultures were taken on treated patients at each visit at intervals of several weeks and at somewhat longer intervals on control patients, throughout the seasons of 1937-1938, 1938-1939 and 1939-1940. A few cultures were taken in 1936-1937. A total of 500 cultures was taken on treated patients during the period of sulfanilamide administration. Twenty of these, or 4.0 per cent, were positive for the beta hemolytic streptococcus (table 3). Eight of the positive cultures were obtained from two persons who had had fairly large numbers of beta hemolytic streptococci in the flora of the throat just preceding the administration of sulfanilamide. One patient (G. D.) had 40 per cent beta hemolytic streptococci in the pharyngeal culture before sulfanilamide was started, and three out of eleven cultures showed 5 per cent of the organism after the drug was started.

R. H., a 17 year old Negro boy, had been hospitalized for two months with his sixth attack of rheumatic fever in six years. Symptoms during the first week in the hospital included sore throat, abdominal pain, painful tender joints and cough

with bloody sputum. He had huge infected tonsils, mitral stenosis and aortic insufficiency with changing electrocardiograms. A pharyngeal culture on admission showed one colony of beta hemolytic streptococci; two subsequent ones showed normal flora. The sedimentation rate, elevated at first, fell to normal three weeks before discharge and there remained.

Ten days after leaving the hospital in December he came to the cardiac clinic. He was symptom free, with a normal

TABLE 3.—Comparison of the Incidence of Positive Pharyngeal Cultures in the Treated and Control Groups

Season	Treated Group During Sulfanilamide Season			Control Group During Control Season

sedimentation rate, and remained so throughout the year. Pharyngeal culture, however, on the first and second visit to the clinic showed 50 per cent and 40 per cent beta hemolytic streptococci. Sulfanilamide was then started; successive cultures of material from the throat during the next fourteen weeks showed the following percentages of beta hemolytic streptococci: 40, 50, 5, 5, 0 and 10. At that point tonsillectomy was performed; culture of the macerated tonsillar tissue showed 50 per cent beta hemolytic streptococci. Subsequent pharyngeal cultures showed only normal flora for the remainder of the sulfanilamide course and through the summer months. The boy took sulfanilamide again the following winter; nine pharyngeal cultures showed normal flora, while one showed 1 per cent beta hemolytic streptococci. He had no recurrence of rheumatic fever.

Aside from these 2 patients who were carriers of beta hemolytic streptococci when sulfanilamide was started, 10 treated patients had single (in two instances, two) positive throat cultures during the four seasons of therapy. The average proportion of beta hemolytic streptococci in these isolated cultures was 9.3 per cent.

In contrast to the carriers G. D. and R. H., mentioned previously, 2 patients who showed positive cultures immediately preceding sulfanilamide therapy became free from beta hemolytic streptococci as soon as the drug was started:

G. H. had 80 per cent and 50 per cent beta hemolytic streptococci ten days before and on the day of starting sulfanilamide. After eighteen days on the drug a culture of material from

TABLE 4.—Occurrence of Major Rheumatic Episodes in the Prophylactically Treated and Control Groups of Patients

Group	Person-Seasons	Major Episodes

Control.....	150	15	10.0
Total.....	229	15	6.6

his throat showed only normal flora, and this state of affairs persisted throughout the season of treatment.

M. H. showed 5 per cent, 40 per cent and 20 per cent beta hemolytic streptococci in three pharyngeal cultures taken three weeks before, two weeks before and the morning before starting treatment. Seventeen days later the culture showed only normal flora, and so remained throughout the season of therapy.

In the control group, 41 of 336 cultures taken during the four control seasons were positive, an incidence of

12.2 per cent or three times that observed in the treated group.²⁰ The positive cultures were distributed among 32 patients; there was no evidence that any of the patients were carriers. Only 2 patients had as many as three positive cultures; these were not obtained on consecutive visits nor was the streptococcus the predominating organism. The average proportion of beta hemolytic streptococci in the positive cultures on control patients was 21.2 per cent, over twice as great a concentration as in the positive cultures of treated patients.

Thus it appears that during the eight month treatment and control periods, pharyngeal cultures positive for beta streptococci were more numerous and more strongly positive among control patients than among treated patients. Did this difference result from the presence or absence of prophylactic treatment or from inherent differences in the two groups of patients? Relatively few cultures were taken during the four "summer" months, and this particularly applies to the control group. However, the fact that of seventy-nine such "summer" and pretreatment cultures taken on patients treated during the "winter" months in 1938-1939 and 1939-1940, fourteen, or 17.7 per cent, were positive strongly suggests that the treated group was at least ordinarily susceptible to harboring the beta hemolytic streptococcus.

Major Rheumatic Episodes.—During the four years of this study, not a single major attack of acute rheumatic fever occurred in any patient while taking sulfanilamide as a prophylactic (table 4). Fifteen major

TABLE 5.—Distribution of Major Rheumatic Episodes Between Two Subdivisions of Control Group

rheumatic episodes were observed among the control cases during the same period, and one such episode occurred during August in a patient who had received prophylactic sulfanilamide the preceding season.²¹ In all, 55 patients received prophylactic doses of sulfanilamide during seventy-nine seasons (charts 1 and 2²²) while 67 patients were observed as controls during one hundred and fifty seasons²³ (charts 1, 2, 3 and 4).

Of the control group, 35 patients never underwent a season of prophylactic treatment (charts 3 and 4); eight major episodes occurred among these patients. The remaining 32 had at some time taken sulfanilamide for one or more seasons and then were shifted to the control group (charts 1 and 2); seven major episodes occurred among control patients of this type (table 5). It is thus apparent that a course of prophylactic treatment has no statistically demonstrable effect on the subsequent appearance of attacks of acute rheumatic fever after sulfanilamide has been withdrawn.

Among the control group, then, fifteen major episodes occurred during a total of one hundred and fifty person-

20. This does not include positive cultures encountered during hospitalization for major and questionable episodes.

21. A "season" indicates the eight month period of prophylactic therapy.

22. A major rheumatic episode occurring during the treatment seasons would have been represented by a black block superimposed on a cross-hatched area. Since no such episodes occurred, this arrangement of symbols does not appear in charts 1 or 2.

23. In 4 cases of death during control seasons, the duration of such seasons was counted as half the normal season for statistical purposes.

seasons, an incidence of one major attack per ten person-seasons. If a similar rate of attack were present among the treated group, eight major episodes among seventy-nine person-seasons would be the normal expectancy. Yet there were actually no attacks among the treated group. The likelihood that this was the result of chance is calculated as $P = 0.003$; in other words, a difference as great as or greater than that observed would have arisen by chance only three times in a thousand assuming that the treated and control patients are comparable groups.²⁴

(May and June). The June attacks occurred early in the month and in two instances at least were preceded by beta hemolytic streptococcus throat infections toward the end of May. C. A. had two attacks in one year, with nearly a three month period of well-being between attacks; L. F. was hospitalized twice in 1939-1940 with a month intervening between hospital admissions, but he was never well, so that this whole period is considered as one major rheumatic episode.

On inspecting charts 1, 2, 3 and 4, one will note that the high incidence of major episodes just before inclu-

§ E. S. R. = erythrocyte sedimentation rate; J. H. H. = Johns Hopkins Hospital; C. C. = Cardiac Clinic; U. R. I. = infection of upper part of respiratory tract.

The details of the fifteen major attacks occurring in the control group are analyzed in table 6, and a summary of the group suffering from recrudescences compared with the treated and control groups is given in table 1. The rate of attacks was highest in 1936-1937, lower in 1937-1938 and 1938-1939 and again high in 1939-1940. The apparent preponderance of attacks in 1940 depended on, first, the high attack rate and, second, the fact that the size of the control group was greater than in any preceding year. Most of the attacks occurred either in early winter (December to February) or late spring

sion of patients in the study is striking and is, of course, due to the fact that patients were selected because they had recently had attacks. The first season such attacks had occurred within three years of admission to the study; thereafter most of the available new patients had had acute rheumatic fever in the hospital within the preceding year. The fact that major attacks seemed more prevalent in both treated and control patients before entering the study than after may be accounted for on three grounds: first, that the patients were selected in such a way that all had had attacks just prior to inclusion in the study; second, that the chances of recurrences diminish with age and with the number

24. Dr. Edwin L. Crosby gave assistance and advice in matters pertaining to biostatistics.

of recurrences; and finally, that while all of the recent major attacks occurring just before and during the study were observed in the hospital, as well as some of the early episodes, other early major episodes recorded in the figures are based on the history as given by the patient, affording some chance for inaccuracy. All these considerations apply equally to treated and

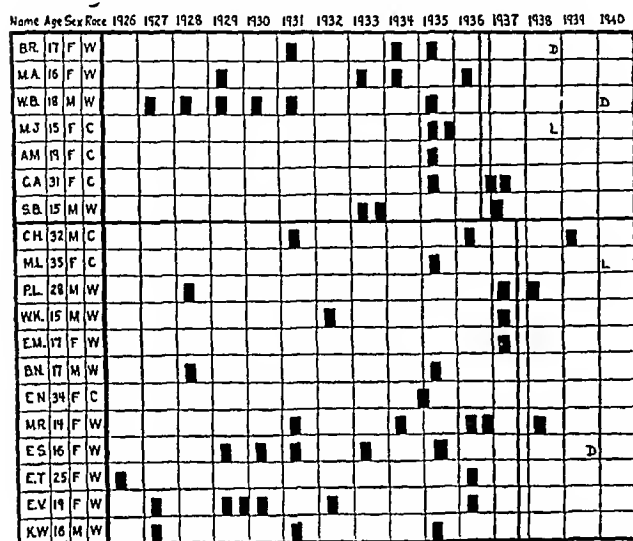

Chart 3.—Major episodes of acute rheumatic fever in control patients who entered the study in 1936 and 1937. The symbols are as given in chart 1.

control patients, and great care was taken to include patients with history of both many and few attacks in both groups.

Minor Rheumatic Episodes.—During the four seasons of observation, only two minor rheumatic episodes occurred among the treated group. Both attacks occurred soon after treatment was begun; 1 patient, F. R., was receiving only one fourth the final daily routine dose.

F. R. was started on 0.3 Gm. of sulfanilamide daily the first season. At the end of a week acute rhinitis without sore throat developed in him, and a week later one knee was painful and swollen for three days, with elevation of the sedimentation rate. The dose of sulfanilamide was subsequently raised.

M. W. began to take 1.2 Gm. of sulfanilamide daily in October 1937. Five days later he had malaise and painful hot wrists. The following day these symptoms had disappeared, but two days later his ankles were painful for a few hours. None of the joints were swollen, and he had no further symptoms.

Among the control patients, six minor recrudescences were noted:

P. L. had pains in his finger joints one day after extraction of an abscessed tooth, and six days later his knees and one wrist were swollen and sore and his sedimentation rate became elevated. He had not been treated with sulfanilamide prophylactically in the cardiac clinic, but he was given 2.4 Gm. of the drug daily for three days by another physician at the time of the dental extraction, beginning the day before the extraction was performed, and received half that dose for two more days.

E. M. had been hospitalized with acute rheumatic polyarthritis and myocarditis and erythema multiforme from January to April 1937. In March 1938 the cutaneous eruption recurred even more severely, continuing until July, associated with polyarthralgia and occasional precordial pain. During June the patient was in bed several days with fever and sore throat.

C. A. had joint pains with elevated sedimentation rate and changing electrocardiograms throughout the winter of 1938-1939.

L. F. had sore throat, cough, low grade fever and mild polyarthritis during April and May 1939, with a sedimentation rate of 30 to 33 mm.

W. K. had polyarthritis in May 1939, following an infection of the upper part of the respiratory tract, with night sweats, malaise and considerable pain and redness of the joints. He went to bed at home for six days. His sedimentation rate, usually normal, remained between 36 and 28 mm. for two months.

J. S., two weeks after one "chest cold" and three or four days after beginning another, had polyarthritis the first week of October 1938, with migratory joint pains and swelling of one knee. The sedimentation rate was 34 mm.

The cases of F. R., M. W. and P. L. suggest that sulfanilamide has little or no prophylactic value if administration is begun two weeks or less before the onset of a rheumatic episode.

Questionable Rheumatic Episodes.—None of the patients receiving sulfanilamide therapy had any febrile or incapacitating illness in which the diagnosis of rheumatic fever was brought into question. (Four patients had clinically typical influenza with leukopenia.) Among the control patients, 5 had illnesses requiring hospitalization in which a relationship to acute rheumatic fever was possible but not certain.

J. S., who has mitral stenosis, was hospitalized in October 1937 with bronchopneumonia. Culture of the sputum showed a small percentage of pneumococcus type IX; beta hemolytic streptococci were not recovered. There were no other signs of rheumatic activity. In 1934 he had had a similar attack with beta hemolytic streptococci present in the pharyngeal culture.

C. A., who had mitral stenosis and first degree heart block, had two attacks of polyarthritis in the spring of 1937. In the spring of 1938 she complained of feverishness, weakness and joint pains. In May 1938 she was hospitalized with fever, arthritis, erysipeloid swelling of the legs, several subcutaneous nodules, tender swelling of a synovial bursa on the back of her hand and a fine papular rash. Sedimentation rate was 32 mm.; culture of material from the throat showed 10 per cent beta hemolytic streptococci. The blood Wassermann reaction, which had been negative the year before, was positive. She received

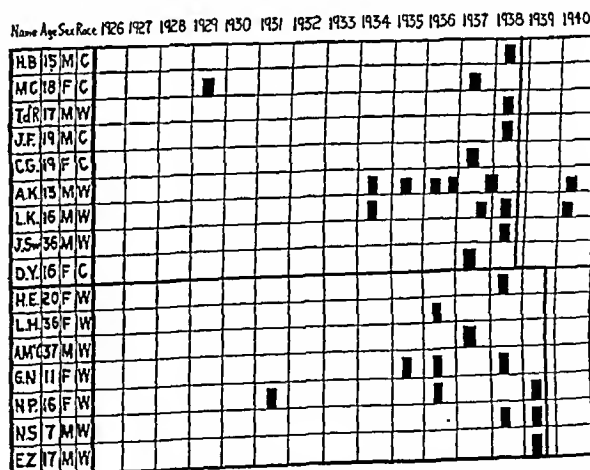

Chart 4.—Major episodes of acute rheumatic fever in control patients who entered the study in 1938 and 1939. The symbols are as given in chart 1.

antisyphilitic treatment and also large doses of salicylates. It was never fully determined whether this attack represented secondary syphilis alone, or rheumatic fever or both.

L. F., who had mitral insufficiency and stenosis and aortic insufficiency, began to have sharp abdominal pain, substernal and precordial pain with some dyspnea early in December 1937. In January 1938 he was admitted to another hospital, with totally irregular cardiac rhythm at a rate of 140, slight orthopnea but no other signs of congestive failure. This was the patient's

first attack of auricular fibrillation. Reversion to normal sinus rhythm with first degree heart block followed a course of digitalis and quinidine.

M. T. was in the Johns Hopkins Hospital for three weeks in November 1938 with lobular pneumonia associated with joint pains and a subcutaneous nodule. No pathogenic organisms were cultured from her sputum.

R. d'A., a white woman of 26 years, who had mitral insufficiency and stenosis, aortic insufficiency and cardiac enlargement, had a hysterectomy in November 1939 to interrupt a pregnancy. Nine days postoperatively fever developed and pain in the lower part of the abdomen, followed by tenderness along the course of the right femoral vein and pain in the axilla on respiration with nonproductive cough. She had signs of consolidation over the lower portion of the left side of the chest, with temperature increasing up to 103.5 F. The diagnosis was thrombophlebitis and pulmonary infarction. By December 11 the symptoms and signs had disappeared, and her temperature had returned to normal. At the height of her fever transient second degree heart block developed in her, and subsequently, prolongation of the auriculoventricular conduction time which persisted for over a month. The T waves remained upright throughout. She had had digitalis at the time of the second degree heart block, but it is doubtful whether she was overdigitalized, especially as her PR interval was still 0.24 on December 27, twenty-four days after stopping digitalis. Similar prolongation of the PR interval occurred during her last attack of acute rheumatic fever in 1936, when she had had no digitalis. Finally, on another occasion when the digitalis dosage was pushed, characteristic T wave changes developed without lengthening of the PR interval.

Other questionable episodes which did not involve hospitalization occurring among control patients were as follows:

E. V. had pain and swelling of the fingers for a few days in the spring of 1939. She was out of town at the time.

M. R., who did not come into the cardiac clinic in 1939-1940, wrote in answer to a follow-up letter, "I had rheumatic fever in December (1939)" but did not describe the attack.

L. J. had bouts of multiple joint pains from October 1939 to April 1940. She was later found to have pyelitis.

R. E. had pain in his right wrist three weeks after the onset of a febrile infection of the upper part of the respiratory tract with a productive cough. The sedimentation rate was 29 mm. three days after the onset of pain.

At each visit patients were specifically questioned concerning the occurrence of epistaxis, joint pains, sore throat, rash, nausea, vomiting, precordial pain, choreiform movements, or other rheumatic symptoms. Among the treated group most of the patients were symptom free throughout the period of therapy. A few each winter complained of mild arthralgia, often in a single joint, without local heat, tenderness or swelling, and in the course of an ordinary cold there might be some soreness of the throat for a day or two. Occasional precordial pain and isolated epistaxis were also noted. No chorea or significant nausea and vomiting were recorded. The only patient who had a cutaneous rash of probable rheumatic origin during sulfanilamide therapy had had the eruption much more markedly before the drug was started:

E. B. had had attacks of erythema multiforme almost every evening for several months while in the hospital during his last acute attack of rheumatic fever, characterized by annular lesions which appeared and faded within a few hours. The lesions had been present frequently during the six weeks between discharge from the hospital and starting sulfanilamide therapy. The lesions recurred but twice, two and a half weeks and four months after beginning the drug, in 1938-1939, once during the summer of 1939 when he was not treated, and twice during the treatment season of 1939-1940. Each recurrence was for a few hours only.

Since the control patients were not all seen as frequently as the treated patients, isolated symptoms were not always recorded as accurately in the control group, but it was our impression that sore throats and epistaxes were more frequent and more severe among the untreated persons.

Prognosis; Deaths.—On entering the study, 4 patients had definite impairment of cardiac functional capacity necessitating some limitation of activity.²⁵ Of these, 2 (L. M. and L. E.) have been receiving sulfanilamide for four and three seasons respectively. The other 2 (L. F., M. T.) were given the drug in 1936-1937 and have been in the control group during the subsequent three seasons. Both of the latter patients have had acute recrudescences of rheumatic fever while in the control group, and L. F. has died of acute rheumatic fever. L. M. and L. E., on the other hand, have had no renewal of rheumatic activity clinically and have shown little or no further impairment of the functional capacity of the heart.

In 2 patients in the control group (B. R. and E. S.) subacute bacterial endocarditis developed, for which they were hospitalized, 1 in this hospital and 1 in the Baltimore City Hospital, with subsequent death and autopsy in both instances. Neither of these patients had ever received prophylactic sulfanilamide. In no patient receiving the drug did subacute bacterial endocarditis develop.

Finally, there were four deaths among patients in the control group, one from acute rheumatic fever and two from subacute bacterial endocarditis, as previously mentioned, and one from an acute illness of uncertain nature (L. F., B. R., E. S., W. B.). There were no deaths among patients in the sulfanilamide group while taking the drug.

COMMENT

The findings in this four year study confirm those reported in January 1939. It is striking that, while major rheumatic recrudescences occurred in 10 per cent of the one hundred and fifty person-seasons observed in the control group, no major episodes occurred during the seventy-nine person-seasons in the treated group. Every effort was made to evaluate the various factors affecting the treated group and control group; these have been set forth in detail in table 1. The treated group contained a slightly higher percentage of patients with organic and functional cardiac disability. In the control series there were more uncooperative patients, but only three major attacks developed among them, which is a smaller percentage than occurred among the cooperative control patients. The factors of nutrition, housing and intelligence were not significantly different in the two groups.

Beta hemolytic streptococci were found in 12.2 per cent of the three hundred and thirty-six pharyngeal cultures obtained from control patients during the months of October through June. It is interesting to compare this finding with two recent studies on the prevalence of beta hemolytic streptococci in cultures of material from the throat of normal persons living in Baltimore. Bourn, Carpenter and McComb²⁶ reported 10.4 per cent positive cultures among 2,812 taken between October and July over a three year period; most of their subjects were medical students;

25. Class II, classification of the New York Heart Association, 1939.

26. Bourn, J. M.; Carpenter, H. M., and McComb, E.: *Streptococcus Haemolyticus (Beta) in the Presence and Absence of Acute Minor Respiratory Infection*, 1928-1931, *Am. J. Hyg.* 17: 761 (May) 1933.

some were dispensary patients. Long and Bliss²⁷ found 10 per cent and 13 per cent of pharyngeal cultures positive for ordinary beta hemolytic streptococci in two smaller groups of normal persons during the winter season. Thus the incidence of positive cultures in normal persons living in Baltimore is almost identical with that found in our control group. Since this is true, the fact that only 4 per cent of the five hundred cultures taken on our treated group of patients were positive gains increased significance. Sulfanilamide prophylaxis apparently caused a substantial reduction in the incidence of the beta hemolytic streptococcus in throat cultures of persons under treatment.

Of considerable interest is the fact that four deaths occurred among the control patients and none among the treated patients, although the latter had equally serious cardiac lesions. Also the fact that 2 of the 4 patients died of subacute bacterial endocarditis, while in no patients under treatment did this serious malady develop, brings up the question of whether sulfanilamide may prevent this complication as well. Our series is too small to bring any statistical evidence to bear on these points.

Since children often have a more fulminating variety of rheumatic fever than adolescents and young adults, and since most cardiac lesions begin in childhood, it seems logical that the sooner prophylactic treatment can be begun the better the results will be. As our study included very few children, we must await other studies to ascertain whether this assumption is correct. The results reported in the preliminary work of Coburn and Moore on children between the ages of 6 and 14 are as good as those of ours in persons of 14 years and over.

SUMMARY AND CONCLUSION

1. Sulfanilamide was given continuously to 55 patients with a recent history of acute rheumatic fever during seventy-nine person-seasons between 1936 and 1940. Sixty-seven patients with similar history, who were given no prophylactic treatment, were observed simultaneously during 150 person-seasons.

2. The drug was taken from November through June, usually in a dose of 1.2 Gm. daily.

3. No serious toxic effects were observed. Mild cutaneous eruptions and some drop in total white blood cell count without granulocytopenia occurred in a few patients. The leukopenia was self limited in duration and was of no apparent clinical significance.

4. Pharyngeal cultures positive for the beta hemolytic streptococcus were less numerous and showed a lower percentage of the organisms among treated patients than among control patients.

5. While taking sulfanilamide, none of the patients had a major attack of acute rheumatic fever or an acute beta hemolytic streptococcus infection.

6. Fifteen major attacks of acute rheumatic fever developed among patients not taking sulfanilamide during the control period. One patient, treated during the winter months, had an acute rheumatic recrudescence in August when he was not taking the drug. Five control patients suffered from acute illnesses which might have been of rheumatic character. One control patient was hospitalized with an acute beta hemolytic streptococcus infection.

7. Subacute bacterial endocarditis developed in 2 control patients.

8. Four deaths occurred among the control group, one from acute rheumatic fever and two from subacute bacterial endocarditis. The cause of death in the other case is uncertain. There were no deaths among persons in the treated group.

Sulfanilamide²⁸ may safely be administered in small daily doses over a long period of time. It appears to be of value in preventing recrudescences of acute rheumatic fever.

THE TREATMENT OF CONGESTIVE FAILURE IN CHILDREN WITH ACTIVE RHEUMATIC FEVER

BERNARD J. WALSH, M.D.

WASHINGTON, D. C.

AND

HOWARD B. SPRAGUE, M.D.

BOSTON

During the past three years we have studied the effects of various drugs on the heart and circulation of forty-four children with congestive failure during active rheumatic fever.¹ It is our purpose in this report to call attention to the aspects of the therapy of congestive heart failure peculiar to children suffering from this disease.

METHODS OF STUDY

More than 200 patients, mostly children, with congestive failure have been given prolonged care at the House of the Good Samaritan from 1920 to 1940. In a series of 44 consecutive patients with heart failure, all of whom were between 3 and 15 years of age, we were able to compare the influence of certain drugs on the failing heart. The effectiveness of a drug was determined by increase in urinary output, lowering of the venous pressure, decrease in the size of the liver and loss of body weight. The usual conditions of absolute bed rest and restriction of fluids (1,200 cc. or less per day, varying with the size of the patient) were enforced throughout the period of heart failure. No salt was added to the diet except that used in cooking. Intake and output of fluids were measured.

CLINICAL OBSERVATIONS

Xanthine Derivatives.—Because of the ease of administration, low cost and good results obtained the drugs of the xanthine group are of much value in the treatment of children with rheumatic fever, in particular theocaine (theobromine calcium-salicylate) and theosodate (theobromine sodium-acetate). We have used theobromine calcium salicylate in twenty-three cases, with a satisfactory response in 13, or 65 per cent. It is in our experience the best tolerated of all members of this group, rarely causing any gastrointestinal upset. The optimal daily dose has been 3 to 5 Gm. (an average of 3 Gm.) divided into three doses. We have used it as long as it was effective, in some cases daily for a period of three to four months. Theobromine sodium-acetate has been used in eleven cases, with an excellent effect in 9, or 82 per cent. The higher incidence of benefit from the use of this drug as compared to theobromine calcium-salicylate does not necessarily indicate that theobromine

28. The sulfanilamide used in these investigations was supplied by the Winthrop Chemical Company, Inc., New York.

sodium-acetate is more efficient in view of the smaller number of cases and the known variability of rheumatic fever. It is well tolerated and without any evident disadvantage when given in the dose of 3 to 5 Gm. daily in divided doses.

Diuretin (theobromine sodium-salicylate) is less effective than the previously mentioned xanthine derivatives, since it frequently causes vomiting when given by mouth. However, when it is impossible to give a diuretic orally, theobromine sodium-salicylate is often effective when administered rectally in doses of 1 to 2 Gm. in tap water three or four times daily.

We have had no success with plain theobromine in the few cases in which we have tried it, chiefly because of nausea and vomiting.

Mercurial Diuretics.—It has been necessary to use salyrgan or mercupurin because of otherwise uncontrollable congestive failure in 27, or 61 per cent, of our patients. Satisfactory diuresis resulted in more than 90 per cent of instances in which these drugs were used when given in the dose of 1 cc. intravenously. In an occasional instance it was necessary to resort to one of these diuretics once or twice a week for several weeks until the patient either improved and was maintained on a xanthine drug or grew worse and died. It was frequently necessary in order to get a good result to precede the mercurial diuretic by 3 to 4 Gm. of ammonium chloride in the previous twenty-four hours. In the treatment of small children 0.5 cc. of mercupurin or salyrgan is sufficient to cause a satisfactory urinary output. We have not had any toxic reactions from these drugs. However, it is unwise to give a mercurial diuretic in the presence of full digitalization, since the mobilization of the edema fluid consequent to the use of the mercurial may lead to intoxication with digitalis. We would advise the omission of digitalis for as long as possible before the administration of mercupurin or salyrgan. Mercupurin in suppositories was satisfactory in seven instances but proved ineffective on three other occasions, possibly because of failure to retain the suppository for a sufficient period. There was mild rectal irritation in 2 patients but no other untoward effects.

Digitalis.—The use of this drug in the treatment of children with rheumatic heart disease and congestive failure has been the subject of considerable controversy. Some authors (Jacobsen and Davison,² Bachmann,³ and Sutton and Wyckoff⁴) have maintained that it is of benefit, while others (Schwartz and Schwedel⁵ and Schwartz and Levy⁶) have concluded that digitalis is not of value in the treatment of heart failure in children.

We have witnessed marked improvement as evidenced by diuresis, loss of edema, decrease in the size of the liver and lowering of the venous pressure in 15 (43 per cent) of the 35 cases in which digitalis was used. We are convinced that digitalis has a definite place in the therapy of heart failure in children although it must be given with greater caution to children than to adults. The lack of response in the majority (20, or 57 per cent) cannot be accounted for readily, except in a few patients

with overwhelming rheumatic infection, since the two groups were comparable in the duration and severity of rheumatic fever and rheumatic heart disease.

It is of considerable interest that the maximum effect was obtained in our patients by doses of digitalis equal to the amount required by adults as calculated by Eggleston's method (1 cat unit, or 1½ grains [0.1 Gm.], of digitalis U. S. P. per 10 pounds [4.5 Kg.] of body weight). This is contrary to the widely held opinion fostered first by McCulloch and Rupe⁷ and later by Jacobsen and Davison² that the effective dose of digitalis in children is 50 per cent to 200 per cent more per unit of body weight than is needed in adults. We have found it not only unnecessary but possibly dangerous to exceed the estimated therapeutic dose of digitalis as determined by Eggleston's rule,⁸ since there seems to be an increased tendency for children with active rheumatic fever to suffer serious cardiac disturbances while under digitalis therapy. It was the appearance of auricular fibrillation in 6 of our patients who were taking digitalis and the return of normal rhythm in 5 of them when the drug was omitted that first impressed us with the unusual responses to digitalis which may occur. In the sixth patient, a 10 year old girl with disease of the mitral valve of six years' duration, the arrhythmia continued until death two weeks after the digitalis was stopped.

Two patients who had tolerated a daily maintenance dose of 1½ grains of digitalis for two weeks had a flare-up of rheumatic fever which coincided with the appearance of auricular fibrillation. In a third patient, who was also receiving a daily dose of 1½ grains of digitalis, auricular fibrillation developed the day after a considerable diuresis from intravenous injections of salyrgan. The fact that auricular fibrillation became manifest in 2 patients at a time when only the estimated therapeutic dose had been reached and in 1 other when the calculated dose was exceeded seems to us to indicate the wisdom of avoiding large amounts of digitalis in children.

Sudden death occurred in 3 patients showing toxic effects from digitalis other than auricular fibrillation (bigeminal rhythm due to ventricular premature beats in 2 patients, and two to one heart block in the third). Another patient, in whom auricular fibrillation had been present within five days of death, died unexpectedly. These experiences have further strengthened our belief that some children with severe rheumatic fever and rheumatic heart disease manifest a peculiar sensitivity to digitalis. While sudden death is not rare in patients suffering from rheumatic heart disease and congestive failure, it generally occurs in those patients who have failed to show improvement or who are growing worse despite all treatment.

In the children whose congestive failure has improved under treatment but who have, as well, signs of intoxication with digitalis, as in the 4 cases just described, one cannot escape the impression that the action of digitalis rather than the rheumatic fever may have been the major factor in the sudden death. Schwartz⁹ was so impressed by the appearance of auricular fibrillation as an early sign of digitalis toxicity in children with rheumatic heart disease and congestive failure, and by

the death of 1 patient so affected, that he concluded digitalis was actually contraindicated in the treatment of children with rheumatic fever, active carditis and myocardial insufficiency. Our experience indicates that when its dosage is carefully controlled digitalis is useful in the treatment of children with rheumatic fever and congestive failure in spite of its potential dangers.

Dosage.—It is our practice to give $1\frac{1}{2}$ grains of digitalis orally three or four times a day until the total dose as estimated by Eggleston's method is reached. We do not hesitate, although it is seldom indicated, to administer the full calculated amount of digitalis in two or three doses orally or parenterally over a period of eighteen to twenty-four hours. The effect of digitalis is then maintained by a daily dose equal to 1 or $1\frac{1}{2}$ grains (0.06 or 0.1 Gm.); the smaller dose is adequate for children between 5 and 10 years of age.

Electrocardiograms should be taken at frequent intervals, at least every three days, until the full dose of digitalis is given, so that its effect, particularly on auriculo-ventricular conduction, may be observed. Disturbances of rhythm and high grade heart block may occur as a result of digitalis in the absence of anorexia, nausea and vomiting. We are so impressed with the need of electrocardiographic studies in children who are receiving digitalis that we would hesitate to use this drug if facilities for taking electrocardiograms at frequent intervals were not available.

COMMENT

Congestive failure in children with rheumatic heart disease seldom lasts less than a month and occasionally is evident for a year (average duration in our patients was three months). That it is of serious prognostic import is indicated by the death of 32 (73 per cent) of our patients, all of whom had congestive failure at the time of death. Seven (16 per cent) have recovered from congestive failure and rheumatic fever and are now well, and it is possible that the remaining 5 (11 per cent) still in the hospital with heart failure may likewise be restored to a relatively normal life. Though the clinical course is essentially dependent on the severity of the underlying rheumatic fever, the amount of heart failure can be controlled in a large measure by use of appropriate therapy. Diuretics of the xanthine group, particularly theobromine calcium-salicylate and theobromine sodium-acetate, are the first choice in carrying out this treatment. If they prove unsuccessful, digitalis may be tried, if one estimates the dose according to the body weight and bears in mind that children with rheumatic fever and congestive failure are especially prone to intoxication with digitalis. The mercurial diuretics are reserved for those in whom heart failure is increasing despite the use of a xanthine derivative or digitalis.

SUMMARY

1. Forty-four children with congestive failure during active rheumatic fever were given various drugs (theobromine calcium-salicylate, theobromine sodium-acetate, theobromine sodium-salicylate, mercupurin, salyrgan and digitalis) for their effect on the heart and circulation.

2. The xanthine diuretics were found to be of greatest value, in particular theobromine calcium-salicylate or theobromine sodium-acetate in the dose of 1 Gm. three times a day. Theobromine sodium-salicylate given by mouth was found less effective but was useful when given rectally.

3. Mercurial diuretics given intravenously are effective in producing diuresis but should not be given immediately after full digitalization because of the danger of inducing toxic digitalis reactions during the loss of fluid.

4. Digitalis proved to be of value, but it was found necessary to use great care in its administration.

CHRONIC ENDEMIC SELENIUM POISONING

A REVIEW OF THE MORE RECENT FIELD AND LABORATORY STUDIES

M. I. SMITH, M.D.

WASHINGTON, D. C.

In 1933 Robinson¹ demonstrated selenium in a sample of wheat which had been grown in southern South Dakota and which had previously been shown by Franke and his co-workers² to be toxic when fed to small animals. These contributions solved the problem of the etiology of the pathologic condition in farm animals known in some of the Great Plains states as "alkali disease"³ and simultaneously opened up the larger and more difficult problem of selenium as a possible health hazard to man. The early investigations of Byers⁴ indicating the natural occurrence of selenium in certain soils of some of the western states and its wide distribution in plants available to man as well as to the lower animals brought the problem to the attention of public health investigators. More recently selenium compounds have also come into use in insecticide sprays on the West Coast, and this has added to the hazard from the naturally occurring variety.⁵ Moreover, Beath and his co-workers⁶ have shown that inorganic selenium compounds, such as are used in insecticide sprays, may be absorbed by certain special plants which in turn may serve as converters into organic compounds more or less readily assimilable by plants used in animal and human nutrition. The extent of the health hazard from the increasing use of selenium in the industries has been discussed by Dudley.⁷ Though chemically the selenium compounds constituting an industrial hazard are quite different from those occurring naturally in endemic areas, there is ample evidence to indicate that toxicologically they are at least qualitatively similar.⁸

THE ABSORPTION OF SELENIUM IN MAN IN ENDEMIC AREAS

Field investigations conducted in 1936 in three seleniferous areas of eastern Wyoming, southern South Dakota and northern Nebraska revealed a more or less universal absorption of selenium among the rural population in amounts sufficient to be excreted in the urine in concentrations varying from about 10 to 200 micro-

grams per hundred cubic centimeters.⁹ It should be added that normally human urine in nonseleniferous areas contains no selenium. Investigations as to the probable sources revealed wide occurrence of the element in foodstuffs of animal origin such as milk, eggs and meats, as well as in vegetables and cereal grains.¹⁰ Analysis of such foodstuffs from endemic areas is given in table 1. Drinking water usually contained none and in the few positive instances it did not exceed from 5 to 30 micrograms per hundred cubic centimeters.

Attempts to correlate clinical evidence of selenium intoxication with the degree of absorption as evidenced by urinary excretion did not yield definite results. Symptoms that might be considered pathognomonic of selenium poisoning could not be discovered. The incidence of vague symptoms of ill health, particularly those suggestive of gastric and hepatic disorders, appeared to be sufficiently high to indicate the probability of cause and effect.¹⁰ Urinary analysis in a series of farm animals with frank symptoms of "alkali disease" showed a selenium content varying from 61 to 300 micrograms per hundred cubic centimeters,¹¹ values well within the limits of those found in human beings from the same or similarly affected areas. Our problem, therefore, resolved itself into ascertaining, first, the relation of excreted selenium to that absorbed and, second, determining the limits of tolerance in experimental animals so that we might arrive at some conclusion as to the probable margin of safety in man and the probable effects that may be expected in case this is exceeded.

RELATION OF EXCRETED AND RETAINED SELENIUM TO THE AMOUNT INGESTED

As stated earlier, the field studies had indicated that man living in selenium-endemic areas may excrete more or less continuously as much as 200 micrograms of selenium per hundred cubic centimeters of urine. The significance of this in terms of selenium absorption was not clear until it was shown by experiments on laboratory animals that the excretion level in the urine bore a definite relationship to the amount ingested. On a uniform daily intake of selenium fed as sodium selenite over a period of months it was found that a balance was soon struck so that from 50 to 80 per cent of the amount ingested was excreted in the urine with much smaller and relatively insignificant amounts being excreted in the feces.¹² The continual feeding of small

output in the urine expressed as micrograms per hundred cubic centimeters in animals fed seleniferous wheat protein was roughly equivalent to the daily dose administered reckoned as micrograms per kilogram of body weight. Only a minor part of that ingested, probably that failing of absorption, was found in the feces, but considerable amounts were found to be retained in the tissues. The liver, kidneys, spleen, pancreas, muscles,

heart and lungs are the tissues storing the most, while bones, skin and brain store the least. Of considerable interest is its accumulation in the hair of animals chronically poisoned with naturally occurring food selenium. This is believed to be as good a criterion of the length of time an individual has been exposed to selenium and the extent of its storage in vital tissues and organs as the excretion level in the urine is an index of the daily absorption.¹⁴

On discontinuance of its administration in experimental animals the excretion level in the urine falls off rapidly in the case of inorganic compounds and more slowly when food selenium has been given, so that appreciable amounts may be found in the urine for as long as six months thereafter.¹³ This is consistent with the tendency of this type of selenium to be stored in the tissues in firm combination with the proteins from which it is but slowly released. Its concentration in the blood, which is about half that of urinary selenium during active ingestion, may amount to twice that of urinary selenium from thirty to forty days after its administration has been discontinued.¹⁴ The problem of its mobilization from the body depots awaits solution.

TOXICITY, CELLULAR CHANGES AND FUNCTIONAL DERANGEMENTS

The older literature on the pharmacology of selenium has been of little help in the present problem for it dealt mostly with the acute effects from toxic or lethal doses.¹⁵ The question of the extent of the hazard to health from continued absorption of small subtoxic amounts from food sources is a difficult one to answer. The problem is rendered even more difficult by the fact that virtually nothing is known of the chemical nature of the compound or compounds naturally occurring in foodstuffs. Several investigators have studied the effects of the continual ingestion of inorganic or food selenium when fed at various levels.¹⁶ These researches are generally in good agreement, indicating that 15 or more parts per million in the diet of the rat is toxic. At this level there is an estimated intake of about 1 to 1.5 mg. per

daily doses of naturally occurring food selenium, as in wheat or oats, to suitable laboratory animals showed a similar relationship of output to intake, though here relatively less was excreted in the urine and more retained in the tissues.¹³ Stated briefly, the selenium

kilogram per day, and with inorganic selenium as sodium selenite the incidence of important pathologic manifestations given in table 2 was found.⁸

The continued ingestion of naturally occurring wheat selenium in rats at a level of from 10 to 15 parts per million with an estimated daily intake of from 1 to 1.5 mg. per kilogram showed liver injury, effusions and anemia as the most prominent pathologic manifestations.¹⁷ Higher laboratory animals appear to be more susceptible to its toxic effects. With the foregoing data as a guide many experiments were conducted on cats and rabbits with graded doses of selenium as it occurs naturally in wheat or oats over a period of many months, in order to ascertain the limits of tolerance and the character of untoward manifestations from doses exceeding the tolerated level. Gastric and hepatic functional tests, plasma bilirubin, urinary urobilinogen and hematologic studies were made from time to time in order to discover the earliest toxic manifestations. At the close of the experiment careful microscopic examinations were made of the tissues to correlate functional derangements with structural abnormalities.

or by the decreased ability to conjugate hippuric acid after the intravenous injection of sodium benzoate and is scarcely detectable by the bromsulphalein test. Abnormalities in bile pigment metabolism are usually absent. At necropsy the liver usually presents some degree of chronic interstitial hepatitis, and occasionally advanced portal cirrhosis.

5. The hematologic results with small doses may be negative or show only moderate reticulocytosis of about 5 to 10 per cent. This is most readily demonstrable in rabbits and rats and is usually a forerunner of the more definite manifestations of hypochromic microcytic anemia seen quite frequently in animals receiving larger doses.

It was pointed out earlier that in our field studies in selenium endemic areas a high incidence of symptoms suggestive of gastric disorders was encountered. We have also found a high incidence of damage to the gastric mucosa in our experimental animals, especially those receiving inorganic selenium. Moreover, some of the early investigations of Mead and Gies¹⁹ and of Jones²⁰ indicated the possibility that selenium com-

The results of this investigation, which are described in detail elsewhere,¹⁸ may be summed up as follows:

1. The susceptibility to small doses of selenium in the range of from 0.1 to 0.5 mg. per kilogram daily is quite variable. Much of this variability appears to be due to dietary factors, as will be pointed out presently. Naturally occurring wheat selenium appears somewhat less toxic than the inorganic selenite or selenate.
2. Doses in excess of 0.5 mg. per kilogram daily, which are reflected by an excretion level of 500 or more micrograms per hundred cubic centimeters in the urine, are likely to be toxic and damaging to the tissues. The pathologic effects are similar to those described for rats.
3. The smaller doses of 0.1 to 0.2 mg. per kilogram daily, reflected by an excretion level of about 100 to 200 micrograms per hundred cubic centimeters of urine, which may be tolerated for many months without untoward effects under favorable nutritional conditions, may nevertheless show evidence of hepatic dysfunction under less favorable nutritional conditions.
4. The chief symptoms of selenium intoxication in cats from the continued daily ingestion of the somewhat larger doses of from 0.3 to 0.5 mg. per kilogram are intermittent anorexia, occasional vomiting and a lowered functional efficiency of the liver. The latter is most readily demonstrable by abnormal retention of intravenously injected rose bengal, less readily by the abnormal retention of intravenously injected bilirubin

pounds might cause a serious reduction in free hydrochloric acid. Experiments on rats and cats receiving both inorganic as well as organic food selenium over periods ranging from ten to three hundred and fifteen days failed to reveal a marked or constant diminution of either free or total gastric acidity as compared with control animals.²¹ Dilute alcohol intragastrically or histamine subcutaneously or both were used in these experiments after the usual fasting period of from eighteen to twenty-four hours. These experiments fail to indicate any diagnostic value in chronic selenosis from the usual type of gastric analysis.

THE TRANSMISSION OF SELENIUM THROUGH THE PLACENTA

Transmission of selenium through the placenta was demonstrated by experiments in rats and cats in chronic poisoning with both inorganic and organic food selenium.²² More selenium was found in the tissues of the newborn when the mother's diet contained organic food selenium than when it contained sodium selenite. In rats fed seleniferous oats during the latter half of the gestation period the young, which at birth constituted approximately 28 per cent of the mother's weight, stored about 14 per cent of the mother's selenium intake.

In 1936 Franke and his co-workers demonstrated congenital malformations in chicks hatched from eggs

of selenized hens.²³ More recently Landauer²⁴ was able to show that chronic intoxication of laying hens with seleniferous wheat resulted in more extreme effects on the progeny of Creeper females than on that of their genetically normal sibs, thus indicating that Creeper mutation exaggerates the interference with normal development produced by selenium. In our experiments we have failed to observe any such congenital malformations or developmental anomalies in the mammalian fetus even under the most rigorous conditions of mating animals of both sexes reared on seleniferous diets from the time of weaning. Young born under such conditions with the mothers continuing to be maintained on the seleniferous diets are vastly more susceptible to its toxic effects compared with normal animals placed on similar seleniferous diets at weaning, but the pathologic manifestations are qualitatively the same.

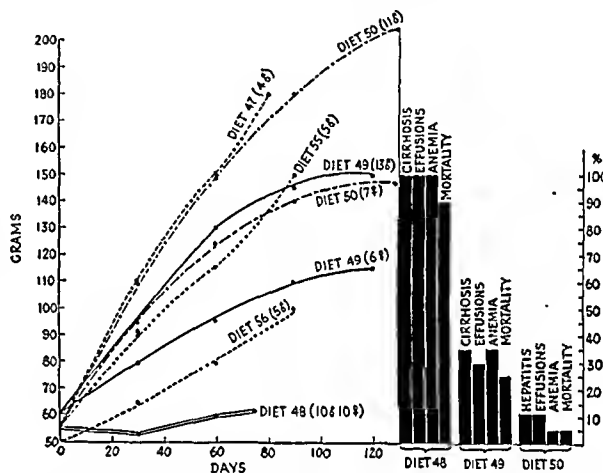

THE EFFECTS OF SELENIUM ON RESPIRATORY AND OTHER ENZYMES

The injurious effect of selenium compounds on certain of the enzymes concerned with cellular respiration was indicated in the work of Collett,²⁵ Labes and Krebs,²⁶ Potter and Elvehjem²⁷ and Stotz and Hastings.²⁸ These investigations showed an inhibition of oxygen consumption by tissues *in vitro* under the influence of sodium selenite, apparently through the poisoning of succinic dehydrogenase. Wright,²⁹ working in this laboratory with sodium selenite and sodium selenate and various tissues, such as liver, kidney, brain and muscle, found an irreversible loss of ability to oxidize naturally occurring substrates after contact with the selenium compounds in sufficient concentration. Definite inhibition of oxygen consumption could be demonstrated with concentrations of the order prevailing in the intact animal receiving a minimal lethal dose of the substance. These experiments indicated no impairment of the cytochrome-indophenol-oxidase but a general poisoning of the dehydrogenating enzymes. Reduced glutathione, which according to Hopkins and Morgan³⁰ could reactivate succinic dehydrogenase previously inactivated by oxidized glutathione, could also protect tissues against selenite provided the glutathione had been added before marked loss of oxygen consumption took place. This suggests the possibility that the injurious effects of the selenium compounds are due to the removal of sulfhydryl groups essential for the oxidative mechanism. In work with other enzyme systems an inhibiting action of selenium on urease was observed³¹ which, according to Sumner and Poland,³² is dependent for its activity on the presence of sulfhydryl groups. No inhibiting effects have been found on choline esterase, catalase or liver arginase.³¹ The last named is of particular interest, for this enzyme may be considered an index of protein metabolism.³³ Liver arginase was unaffected by inorganic selenium compounds *in vitro* and was apparently augmented in

some instances after the ingestion of seleniferous wheat.³¹ These results are consistent with the observation of Cathcart and Orr³⁴ of an increased urea and nitrogen output in the urine of dogs after the subcutaneous injection of sodium selenite and perhaps indicate a better utilization of the proteins in a compensatory manner when the carbohydrate metabolism is necessarily impaired as a result of interference with the dehydrogenation of intermediary carbohydrate metabolites.

THE INFLUENCE OF DIETARY PROTEIN ON THE CHRONIC TOXICITY OF SELENIUM

Last year experiments were reported indicating that dietary protein had a significant influence on the toxicity of naturally occurring wheat selenium in rats.³⁵ It was shown that 10 parts per million of wheat selenium fed in a diet containing 10 per cent protein was highly toxic and damaging to the tissues whereas the same amount of selenium fed in an isocaloric diet containing an additional 20 per cent protein in the form

Effects of cystine and methionine and of graded increments of protein on the chronic toxicity of sodium selenite. Experiments 56, 55 and 47 represent average weight curves of groups of rats on control non-seleniferous low protein diet (7 per cent) alone and when supplemented with cystine or with cystine and methionine respectively. Experiments 48, 49 and 50 contained 15 parts per million of selenium as sodium selenite, the first containing 7 per cent protein supplemented with cystine and methionine to a level equivalent to that of 30 per cent casein, the second containing 13 per cent protein with cystine and methionine as in the preceding and the third containing 30 per cent protein with no additional cystine or methionine. The mortality and incidence of pathologic involvement for the three sets of experiments are shown to the right.

of casein scarcely produced any toxic effects. It appeared from those experiments that within certain limits the toxicity of food selenium is determined by the protein-selenium ratio in the diet rather than by the level of intake. The data available at that time indicated that a seleniferous diet with a protein-selenium ratio of 1:100 as expressed in terms of grams of protein to micrograms of selenium per hundred grams of diet is highly toxic, while a similar seleniferous diet with a protein-selenium ratio of 1:33 or better may be tolerated with relative impunity. Recently this has received confirmation in the experiments of Lewis, Schultz and Gortner³⁶ and of Gortner.³⁷ Moxon, it should be added,³⁸ had also previously reported suggestive though inconclusive experiments of a similar nature.

We have now confirmed and extended those earlier observations to include several other proteins besides casein and to include data on the effects of protein and certain amino acids on the chronic toxicity of inorganic selenium.³⁹ These experiments are published elsewhere in detail and will be mentioned here only briefly. They have shown, as may be seen in table 3, that all the proteins examined—wheat protein, lactalbumin, ovalbumin, the proteins derived from brewers' yeast and from desiccated liver, and even the biologically inferior protein gelatin—afford protection against the toxic effects of wheat selenium. The amino acids lysine and methionine, both of which are relatively low in the wheat protein used at the 7 per cent level in the basal diet, have not shown any beneficial effect when used as supplements. Glucosamine, a substance which in some unpublished experiments has been found to antagonize intravenously injected sodium selenite to some extent, appears to have afforded also a partial protection against the chronic toxic effects of wheat selenium.

The experiments with inorganic selenium when fed at a level of 15 parts per million as sodium selenite in diets with graded increments of the protein casein with or without cystine and methionine supplements are illustrated in the accompanying chart. The composition of the experimental diets is given in table 4. They show conclusively that the degree of protection is related

to the quantity of protein in the diet while cystine and methionine in amounts sufficient to support normal growth in rats on a low casein diet fail to mitigate the toxic effects of selenium.

The mechanism of the protein-selenium antagonism is still a matter of conjecture. It may be, as has been suggested previously, that ultimately an explanation will be found in the differential action of selenium compounds on enzymes concerned with metabolic processes.³⁵ Their inhibiting effect on certain of the respiratory enzymes, more particularly those concerned with dehydrogenation of intermediary carbohydrate metabolites, has been pointed out. Equally interesting is the failure of selenium to affect adversely liver arginase, an enzyme concerned in protein metabolism.

Whatever the explanation for this antagonism may be, it is a matter of considerable practical interest. Moreover, additional evidence has been rapidly accumulating, emphasizing the importance of dietary protein in the prevention of liver injury from other toxic agents. Goldschmidt, Vars and Ravdin⁴⁰ have recently reported a protective action conferred by high dietary protein against the liver injury quite different from chloroform, a type of liver injury quite different from

that produced by selenium.⁴¹ Miller and Whipple⁴² have similarly reported liver injury in the dog from chloroform anesthesia to increase in extent as the protein body stores were depleted. Messinger and Hawkins⁴³ also concluded that the extent of liver injury produced by arsphenamine in dogs is related to the diet and that protein is most effective in preventing it. Whether these are due to specific detoxification by protein or to accelerated regeneration of liver protein needed for repair is not certain. In the present instance the protective action of protein would seem to be a true detoxification since all the known toxic manifestations of selenium poisoning, the effusions, the anemia, the impairment of growth, as well as the liver injury, are equally prevented. The recent observations by Meyer⁴⁴ concerning an increased resistance to diphtherial toxin in rats on a diet rich in protein may also be mentioned in this connection. It is clear that the role of dietary protein in intoxications will require further elucidation.

SUMMARY AND CONCLUSIONS

Though human poisoning in selenium endemic areas from the ingestion of naturally occurring seleniferous foodstuffs has not been definitely established, the evidence of absorption of selenium in man in such areas, sometimes in amounts sufficient to cause harmful effects in experimental animals, appears to be conclusive.

The positive diagnosis of chronic endemic selenium poisoning in man is difficult. Careful consideration of the experimental data on the metabolic fate of selenium in the body and its toxicologic effects as outlined herein will suggest the clinical and laboratory procedures to be employed in the tentative diagnosis of suspected cases.

ABSTRACT OF DISCUSSION

DR. J. H. STERNER, Rochester, N. Y.: During a routine survey of potentially hazardous chemical exposures, selenium was found in the urine of a chemist who was synthesizing an organoselenium compound. In the subsequent studies the advice and help of Dr. Smith and his associates have been invaluable, and I want to take this opportunity to express our appreciation. His comprehensive paper on the toxicology of selenium is so adequate that I shall confine my remarks to a few supplementary studies. Chemists synthesizing methylbenzoselenazoles absorbed and excreted in the urine considerable amounts of selenium. Protective devices such as rubber and synthetic rubber gloves give only temporary protection, as the compound readily penetrates them. By requiring frequent changes of new gloves, protective cream and scrupulous care in handling, the absorption has been materially lessened, but complete prevention of such absorption and excretion is not yet accomplished. There have been no symptoms or signs suggestive of toxic effects in any of the workmen so exposed, nor have serial comprehensive blood studies or hepatic and renal function tests indicated any injury. In one case the urinary excretion averaged 5 mg. of selenium a day for a period of a week; I believe this is a greater amount than has been reported previously in the human being. To demonstrate the skin absorption I dropped 0.1 cc. of the selenazoles (the vapor pressure is negligible) containing about 50 mg. of selenium on my hands, removing it by thorough scrubbing after thirty minutes. During the next four days over 5 mg. of selenium was excreted in the urine, with trace amounts only in the stools. Animal studies have shown the low toxicity

of selenium as the selenazole compared with the inorganic selenate; the LD₅₀ dose for both mice and rats is about 120-130 mg. per kilogram, while that for sodium selenate is 3-5 mg. (Se) per kilogram. The rapidity of excretion may partly explain the low toxicity. In animals, 80 to 90 per cent of the intramuscularly injected selenium (as selenazole) is recovered in the urine within forty-eight hours after injection. The retention of selenium in the tissues after selenazole absorption is small in contrast with that of inorganic selenium compounds or the naturally occurring organic ones. The tissues of rats killed one week after the last daily injection of five successive doses of 5 mg. each contained a total of 10 to 15 micrograms in the liver, traces in the kidney, none in other tissues (including the muscle site of injection).

SURGICAL METHODS FOR RELIEF OF PAIN

FRANCIS C. GRANT, M.D.
PHILADELPHIA

Cancer is only too frequently accompanied by intractable pain. Should reliance be placed on morphine and its derivatives to allay suffering, or should an attempt be made to relieve the pain by blocking afferent pathways leading from the involved area? The pain from cancer is constant and harrowing without surcease by night or day. Relief afforded by morphine is intermittent; pain ceases when the drug takes hold, then reappears. The patient bears with it as long as he can, then begs for more morphine. But section of afferent pathways, carefully planned and properly performed, can result in complete and permanent relief of pain.

Unfortunately, however, the problem is not as simple as it seems. The methods at one's disposal for the relief of pain are not completely satisfactory. Chordotomy, rhizotomy, section of the branches or sensory root of the trigeminal nerve or injection of alcohol into the spinal subarachnoid space all involve the patient in definite hazards. Chordotomy, rhizotomy or section of the trigeminal root imply a major surgical operation with its attendant risks in persons already debilitated by malignant disease. The anterolateral columns lie adjacent to the pyramidal tracts. A badly placed incision in the cord can result in motor weakness in the extremities. Furthermore, bilateral chordotomy is followed in at least 10 per cent of cases by urinary retention, temporary or permanent. Rhizotomy causes complete loss of all modalities of sensation. If it is performed for pain in the arm due to involvement of the brachial plexus consequent on metastasis from mammary cancer, the arm and hand are rendered useless, for although they can be moved no sense of their position remains. Subarachnoid injection of alcohol may paralyze motor as well as sensory nerves and cause urinary retention or weakness in the lower extremities.

The problem of relief of pain is further complicated by the spread of the cancer with the involvement of afferent pathways adjacent to those severed. A uterine or prostatic cancer may cause intense pain in one flank or down one leg. A unilateral chordotomy or subarachnoid alcohol block may give relief for two or three months. Then, as the growth spreads, equally severe distress may appear on the opposite side.

From the practical standpoint, therefore, the decision to attempt to relieve pain by blocking afferent pathways must rest on a number of factors: the position and rapidity of growth of the cancer; the probable period of life expectancy of the patient; the amount and location of the pain; the patient's reaction to it, and the dosage of opium necessary for its control. Finally the patient's general condition as an operative risk requires careful consideration before radical surgical intervention is proposed. Roentgenograms of the chest should always be taken to determine the presence or absence of pulmonary metastases. If the lungs are involved or if the sufferer's general physical condition suggests a life expectancy of less than three months radical surgical intervention should not be attempted unless the pain is devastating. Under such conditions an attempt to block afferent pathways by the injection of alcohol into the subarachnoid space or further recourse to morphine is indicated.

The purpose of this article is to show what can be done for relief of pain by interruption of sensory pathways, the hazards involved and what justification exists for suggesting these procedures rather than continuing

with morphine or dilaudid hydrochloride sedation. Three groups of patients have been selected: those with pain in the face and neck due to cancer of the face, jaw, mouth and sinuses with or without metastases to the cervical glands; those with pain in the arm from mammary cancer or axillary or supraclavicular metastases involving the brachial plexus, and lastly a group with abdominal or pelvic disease producing pain anywhere below the ensiform process.

In the first group the afferent pathways involved comprise the trigeminal and glossopharyngeal nerves and the upper four or five cervical posterior roots. Pain within the trigeminal distribution can be handled by blocking its various branches or sectioning the posterior root. If the growth is in the base of the tongue or tonsillar pillars so that swallowing is painful, the glossopharyngeal nerve must also be sectioned. Extension of the pain into the neck demands cervical rhizotomy. The only pain accompanying cancer of the head and neck which cannot be alleviated by block of the appropriate afferent pathways is that which is referred deep in the ear.

In this group are included one hundred and eight alcohol injections into one or more of the divisions of the trigeminal nerve and forty-nine operative procedures directed against the fifth and/or ninth cranial nerves with or without cervical root section. Reference to

tables 1 to 6 will show the results of various methods of attack on afferent pathways leading from malignant disease in different areas of the face and neck. As might be expected, cancer situated within the sensory area supplied by the second division of the fifth cranial nerve was most successfully handled; first because the central position within the sensory area of this nerve

allows for an ample surrounding area of anesthesia if the whole root is cut, and hence the growth must spread wide and rapidly to reach a sensitive zone; and second because in the surgeon's hands the second division of the trigeminal nerve can be more accurately blocked than the third. Alcohol block of the second and third divisions may be more difficult when a neoplasm is present. Not infrequently the cancer may dislodge the nerve from its normal anatomic position. Cancer of the side of the tongue, floor of the mouth or tonsil pro-

duced pain which was difficult to relieve until Fay,¹ Stookey² and Dandy³ showed that severing the ninth and upper cervical roots in addition to the fifth gave excellent results. A unilateral suboccipital craniectomy with or without midline extension depending on the need for cervical rhizotomy must be performed in these cases. Recently in 10 consecutive cases I have substituted section of the descending root of the fifth nerve in the medulla as suggested by Sjöqvist⁴ (medullary tractotomy) for section at the pons. In 9 of the patients the consequent relief of pain was highly gratifying. In table 6 all operative procedures are grouped together whether a transtemporal approach to the sensory root of the trigeminal nerve or a unilateral suboccipital approach to the fifth, ninth and upper cervical posterior roots was performed. The operative mortality is high (18 per cent), but the percentage of complete relief from pain (80 per cent) is satisfactory. Many poor operative risks were accepted in this group, which fact accounts for the high mortality.

Cancer of the breast with metastatic spread into the brachial plexus above or below the clavicle is included in the second group of cases. Direct injection into the plexus of alcohol has never been successful in my experience. High chordotomy at the third cervical segment has been carried out on three occasions but only once with satisfactory relief of pain. This should be the operation of choice, for the sense of touch and position in the arm and hand is spared and its usefulness unimpaired. The last 3 patients under my observation with axillary metastasis causing pain in the arm had pulmonary metastasis as well and consequent loss of movement of the diaphragm. A high cervical chordotomy seemed therefore contraindicated, for the motor pathways to the still functioning diaphragm might be damaged. Rhizotomy of the posterior spinal roots from

the third cervical to the second thoracic segment seems the operation of choice. This is not an altogether satisfactory procedure because it necessitates a wide laminectomy of seven vertebrae and the section of eight posterior nerve roots, a serious operation on a debilitated patient. Interruption of this number of roots is essential for complete relief of pain. If fewer roots are cut the area of anesthesia may not be sufficiently extensive to relieve the pain completely. Furthermore, as has been stated, the hand and arm are entirely insensitive and completely useless. As soon as the patient is up and around after the operation, the arm should be supported in a sling. Unless this detail is carried out the dead arm drags on the neck and shoulder, annoys the patient and may cause a dull ache in the neck and back. In this series fifteen cervicothoracic rhizotomies have been performed with two fatalities. In 8 cases the pain was entirely relieved; in 5 pain reappeared in the supraclavicular area because of the upward spread of the cancer.

Pain due to malignant disease referred to any area below the ensiform process is most effectively relieved

by unilateral or bilateral section of the anterolateral columns of the spinal cord (chordotomy). The segregation of afferent pain fibers in the anterolateral columns of the spinal cord was suggested by Spiller⁵ in 1905, and their section for relief of pain, first carried out by Martin⁶ at his suggestion in 1912. Frazier⁷ published the first large series of cases in which pain was relieved by this means.

Chordotomy is an ideal operation when the incision is limited solely to the anterolateral columns of the spinal cord. The hazards connected with the procedure are that the pyramidal tracts lying posterior to the anterolateral columns may be involved with consequent motor weakness in the legs; that the pain tracts may not be completely severed if the section is not carried to the proper depth and hence relief of pain is not complete, and that if bilateral chordotomy is done these

hazards are doubled and, in addition, if the section is carried too far anteriorly on both sides the fibers mediating sphincter control may be damaged, with retention of urine as a further complication. However, the landmarks for the section of the anterolateral columns are

definite, the point of the attachment of the dentate shows the level of the anterior border of the pyramidal tracts and with experience motor weakness should always be avoided. Furthermore, with the use of local anesthesia (section of the tracts is not painful) and with repeated testing of the sensory level as the incision is deepened the necessity for too extensive section can be easily avoided. When the sensory level as determined by

immediate tests on the operating table is above the area to which the pain is referred, the incision into the cord is of sufficient depth. A unilateral chordotomy is always to be preferred to bilateral section. However, nice judgment is required in reaching this decision. Particularly is this true when the cancer involves the genital or urinary tract. While the pain may be unilateral when the patient is first seen, experience with this problem soon shows that as the cancer spreads the opposite side may become involved. A careful

estimation should be made of the exact location and radiation of the pain. Only too often patients complain bitterly of pain in one flank or leg, but after repeated and detailed questioning they finally admit that, while the major pain is on one side, occasional twinges are noted on the other. A unilateral chordotomy or subarachnoid block may completely relieve this major pain, but within six or eight weeks the minor contralateral pain hitherto unnoticed now reaches major proportions. My own experience is that unilateral chordotomy should be done and repeated on the opposite side if this situation occurs. The patient's family should always be warned that this may be necessary if an increase in the size of the growth causes spread of the pain or if the original pain was bilateral although referred chiefly to one side.

Fig. 1.—Patient with sarcoma of the parotid gland with pain in the distribution of the trigeminal nerve. Complete relief occurred after section of the descending sensory root of the fifth cranial nerve in the medulla (medullary tractotomy).

Taylor^s has shown that a unilateral laminectomy can easily be done. At present I perform a unilateral laminectomy of the second and third thoracic vertebrae. The muscles on one side only are separated from the spines. Ample exposure for section of the cord at the third or fourth thoracic segment can thus be obtained. Since the muscles on one side alone are disturbed postoperative pain and disability are greatly decreased. For bilateral chordotomy the first to the fourth spines and laminae are removed and sections made at the second thoracic segment on one side and the fourth on the other. If a section is made at exactly the same level on each side a transverse myelitis can occur.

^s Taylor, A. S.: Unilateral Laminectomy, *J. Nerv. & Ment. Dis.* 29: 257, 1910.

Tables 7 to 10 give the statistical results with unilateral and bilateral chordotomy.

Injection of absolute alcohol into the subarachnoid space has been performed one or more times on 31 patients. In 15 cases relief of pain was satisfactory, in 6 the relief was partial, and ten injections were

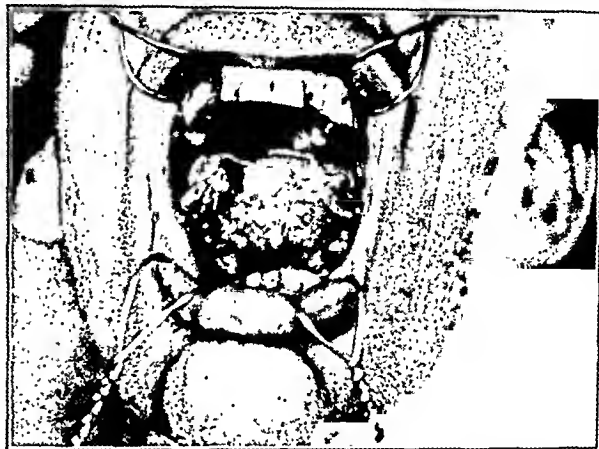

Fig. 2.—Lesion at the base of the tongue requiring section of the fifth and ninth nerves and upper cervical roots for relief.

entirely unsuccessful. In a patient in whom the alcohol (12 minims [0.74 cc.]) was introduced into the mid-thoracic region a partial weakness of one leg developed and persisted for about a year. A second patient had partial paralysis of both legs and complete relaxation of the sphincters after the introduction of 16 minims (1 cc.) of absolute alcohol into the lumbar subarachnoid space. Pain in this case was unaffected.

In the past years unilateral chordotomy has only rarely produced loss of sphincter control. However, recently in 3 of 4 cases in which unilateral chordotomy was performed after unsuccessful attempts to relieve the pain by injection of alcohol into the subarachnoid space, sphincter control was lost. In 2 patients return of function occurred within a month, but the third seems to have suffered permanent damage. The alcohol injections interfere with

sphincter control on the side to which the pain is referred without necessarily relieving the pain. If now a chordotomy is carried out, of course on the contralateral side, the sphincter fibers on this side may be damaged and the result may be complete loss of sphincter tone.

Fig. 3.—Same patient as in figure 2 with anesthesia produced by the procedure outlined. Complete relief of pain.

this operation whereas Tönnis⁸ and Dott⁹ have reported successful outcomes by simply covering the aneurysm with muscle tissue. All the methods mentioned leave much to be desired either because of limited applicability or effectiveness or because of the severity of complications.

A new operative approach has now become available as a complement to existing methods through the work of Blakemore and King¹⁰ on the treatment of aneurysm of the aorta. They devised a practical, successful way to introduce wire into the aortic aneurysm and induce clotting by electrothermic coagulation. The practicability of the procedure depends on the observation by Blakemore and King that fast moving blood will not clot when the wire is heated, whereas the slower moving blood outside the main current will clot. The unusually good results obtained by these workers suggested the application of the method in treatment of aneurysms of the internal carotid artery within the skull. This has been accomplished in the following case:

REPORT OF CASE

The patient's first admission was on April 17, 1937, and her last discharge on Oct. 31, 1939.

History.—R. K., a Jewish schoolgirl aged 15, first appeared at the Vanderbilt Clinic, Sept. 25, 1936, complaining chiefly of diplopia, nausea and vomiting for five months. The family history and personal history were noncontributory. Her previous health and illnesses were irrelevant except for a brief unexplained convulsion as a baby and momentary generalized headaches every one to three months for the four years preceding the present illness, to which the patient paid no attention. The menses were normal, regular every twenty-eight days and moderate. The best and the present weight was 127 pounds (57.6 Kg.).

Fig. 1.—Lateral view of skull, March 17, 1938, showing status of sella turcica just prior to ligation of both common carotids.

The patient was in perfect health, an athletic, vigorous schoolgirl five months before she was seen. At that time, during

a vigorous game of handball, she was suddenly seized by a severe pain in the right orbit and right temporal region. Despite bed rest the headache remained intense. Two days after onset, diplopia occurred when she looked to the right and there was persistent nausea and vomiting. An appendectomy was performed at a neighborhood hospital. Symptoms slowly improved during the next five weeks, but after a few weeks in the

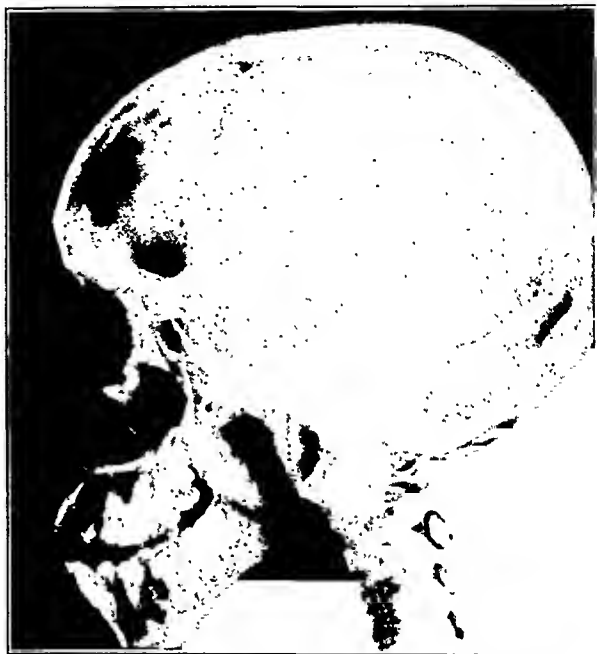

Fig. 2.—Lateral view of skull, Dec. 8, 1938, showing spread of destruction within the sella turcica and into sphenoid sinuses, despite ligation of both common carotid arteries.

country the headache and diplopia returned plus paresthesias of the face and right side of the body, causing the patient to come to the Vanderbilt Clinic five months after onset. The only positive finding on physical examination was a right pupil slightly greater than the left, and questionable hyperesthesia of the right side of the face. Stereocentgenograms of the skull showed no abnormality. No diagnosis was made. A sudden remission of all symptoms except the diplopia then occurred and lasted until April 1937, one year after onset. Severe headaches now reappeared in the right temporal region and also in the occipital area. The patient reappeared in the clinic and was admitted to the Neurological Institute.

First Admission to the Neurological Institute (from April 17 to May 18, 1937).—Physical examination showed that at this time the patient, aged 16, was well developed and well nourished and appeared in good health. The blood pressure was 114 systolic, 74 diastolic. She weighed 127 pounds. There were diplopia, ptosis of the right upper lid, paralysis of the right abducens, paresis of the levator and superior oblique muscles on the right and weakness of the right internal and superior rectus muscles; the right pupil was slightly larger than the left; the fundi and visual fields (involvement of third, fourth and sixth cranial nerves on the right) were normal. There was also a small area of numbness, hyperesthesia and hyperalgesia on the right side of the face from the lateral side of the nose below the eye and over the maxilla along the zygoma to the ear. The thyroid was normal. The rest of the physical examination was negative.

Laboratory examination showed hemoglobin 74 per cent, red blood cells 4,120,000, white blood cells 8,900, polymorphonuclear leukocytes 61 per cent and blood urea nitrogen 10 mg. per hundred cubic centimeters. Fasting blood sugar was 85 mg. per hundred cubic centimeters. The urine showed no abnormalities; the blood Wassermann reaction was negative (both antigens). Spinal fluid was at a pressure of 386 mm. of water. The gold curve was 110000000. The Wassermann reaction of

the spinal fluid was negative; analysis showed lymphocytes 2, globulin 0, protein 13 mg. per hundred cubic centimeters. Roentgenograms of the skull (Dr. C. G. Dyke) showed atrophy of the anterior and posterior clinoids with destruction of the lateral and inferior wall of the right optic foramen to coalesce with the superior orbital fissure. Encephalograms (Dr. Dyke) after injection of 60 cc. of oxygen showed that the cisterna chiasmatis, particularly on the right side, was lifted up by a

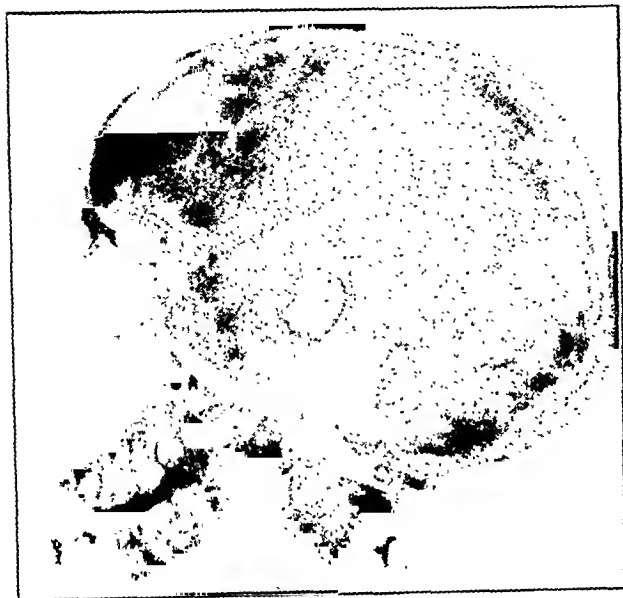

Fig. 3.—Lateral view of skull, Oct. 21, 1939, showing no further spread of area of destruction within the skull since examination April 13, 1939 (fig. 5).

small mass, thought to be an aneurysm of the right internal carotid artery. The olfactory test gave negative results and audiograms were normal.

A metal clip was placed by Dr. Deery on the right internal carotid artery in the neck and partly closed May 14. The closure was completed five days later. Symptoms did not improve during her two weeks in the hospital after the operation.

June 21 the patient paid a follow-up visit to the clinic. She now complained of amenorrhea since her operation (gynecologic examination revealed no pathologic condition at this time), anorexia, loss of weight and strength, constipation and mild pain in the lower abdominal region. There was also some nausea and "dizziness" when she sat erect.

*Second Admission to the Neurological Institute (from June 25 to 27, 1937).—*The patient by now appeared sallow, pale and chronically ill. A bruit synchronous with the pulse was heard over the right eye. Otherwise the examination was as before. The blood pressure was 120 systolic, 70 diastolic, and she weighed 116 pounds (52.6 Kg.). The laboratory observations were noncontributory. The patient was discharged without especial treatment.

A second remission occurred for three months, until September 12, seventeen months after onset, when the appearance of persistent vomiting and the return of her previous symptoms led to her first admission in Presbyterian Hospital for an investigation of the gastrointestinal tract. No abnormalities different from those already mentioned were noted.

The patient complained once that her right eye was "bulging," at which time a bruit was heard. Both the bulging and the bruit disappeared and the patient was discharged, October 18, much improved.

*Third Admission to the Neurological Institute (from Dec. 7 to 21, 1937).—*This admission was arranged because of the return of all her symptoms a short time after discharge from the Presbyterian Hospital.

The patient was now too weak to walk. The rest of her conditions were as brought out before. She weighed 112 pounds (51 Kg.). The spinal fluid pressure was 450 mm. of water.

Laboratory examinations showed hemoglobin 72 per cent and red blood cells 3,920,000; the white blood cell and differential

counts were normal. The urine was normal except for a faint trace of albumin; microscopically there were a few hyaline casts. Blood urea nitrogen was 14 mg. per hundred cubic centimeters. The fasting blood sugar was 85 mg. per hundred cubic centimeters. The spinal fluid was normal as before. Roentgenograms of the skull (Dr. Dyke) in the anteroposterior and the postero-anterior position and right stereoroentgenograms now showed the entire right clinoid process to be destroyed and the right half of the tuberculum sellae to be eroded. The left anterior clinoid process appeared rather sharp and the posterior clinoids and dorsum were slightly atrophic. The pineal was in the midline and normal. Encephalograms (Dr. Dyke) after the injection of 60 cc. of oxygen now showed that the right side of the cisterna interpeduncularis was more markedly displaced upward than before. The sella turcica had increased in size since the first examination and the right anterior clinoid process was markedly decalcified and displaced upward. The impression was that there was an aneurysm of the right internal carotid artery progressing despite ligation of the homolateral artery in the neck.

Eye consultation showed no progression of the optic changes previously described. Visual fields were normal; the exophthalmometer readings were 20 mm. for each eye at 110 mm., probably normal. No further therapy of the aneurysm was considered, so the patient was transferred to the Presbyterian Hospital for treatment of the persistent nausea and vomiting of all she ate.

*Second Admission to the Presbyterian Hospital (from Jan. 8 to June 17, 1938).—*On physical examination the patient was very pale, almost waxen colored, and dehydrated, with a red tongue and dry lips. Examination otherwise was as before except for a soft systolic murmur at the base of the heart.

An electrocardiogram showed the T wave iso-electric, in leads 2 and 4 and inverted in lead 3, indicative of some heart muscle damage. The circulation time was twenty-seven seconds (decholin). The blood Wassermann reaction was negative. The blood group was O; the basal metabolic rate was from -30 to -43 . X-ray examinations of the chest, abdomen and gastrointestinal tract were negative. Gastric expression with histamine was normal. The fasting blood sugar was 73 mg. per hundred cubic centimeters. Complete blood partition showed normal values.

The diagnosis of Simmonds' disease due to destruction of the anterior hypophysis within the sella by pressure of the aneurysm was made in view of the complete syndrome—amenorrhea, anorexia and vomiting, loss of weight, a basal metabolic rate of -43 , flat dextrose tolerance curve and low blood pressure (most readings less than 100 systolic during her stay).

Fig. 4.—Views of orbit (courtesy Dr. Raymond Pfeiffer), Dec. 7, 1938, showing defect in lateral aspect of posterior wall of right orbit, normal optic canal in left orbit.

Attempts at treatment of this syndrome with thyroid, adrenal cortex extract and anterior hypophysial extract were uniformly unsuccessful as judged subjectively, by examination, blood pressure, basal metabolic rate and dextrose tolerance tests. Thyroid caused severe toxic symptoms before much alteration of the basal metabolic rate had occurred. Adrenal cortex extract showed no effect. Progressively increasing doses of anterior hypophysial growth extract resulted in no change, the attempt being abandoned when the largest dose, of 30 cc., resulted in

immediate collapse and shock. The vision in the right eye was at first blurred. A persistent bruit synchronous with the pulse was heard over the nonpulsating right eye globe. Exophthalmometer readings showed the appearance of exophthalmos, 28 mm. for the right eye and 23 mm. for the left eye. X-ray films of the orbit (Dr. Raymond Pfeiffer of the Institute of Ophthalmology) showed an advance of the area of orbital obstruction (fig. 4) as well as destruction of the base of the skull, forming a large defect at the orifice of the right carotid canal merging with the foramen lacerum. The changes in the region of the sella were further increased (fig. 1).

In view of the advance of the aneurysm, further ligation of the carotid arteries was carried out in four stages by Dr. J. M. Hanford of the Second surgical division. The first stage was done, February 24, by ligation of the right external carotid and superior thyroid arteries; the second stage, April 7, by partial occlusion by a Matas-Allen band of the common carotid artery; the third stage, April 15, by ligation of the left external carotid and left superior thyroid arteries, and the fourth stage, April 26, by an attempt at complete occlusion of the left common carotid artery, but immediate loss of consciousness prevented this. On June 1 the procedure was completed uneventfully, two years and two months after the first symptom.

The vision in the right eye, which had been blurred on entry, was noted to be absent May 1, with blurring of vision on the left. The patient's food intake ranged from 500 to 1,300 calories every day, averaging about 800 calories. The blood pressure ranged from 88 systolic, 68 diastolic, to 112 systolic, 84 diastolic, but was on the low side at discharge at the end of June 1938, at which time the patient's weight was 98 pounds (44.5 Kg.). Headaches were less severe and vomiting had mostly ceased, but weakness and a chalky pallor persisted. There was no return of the menses.

Third Admission to the Presbyterian Hospital (from Aug. 2 to 10, 1938).—The patient was admitted for a check-up and also because of eponychia of both great toes, one and one-half months after operation. There was a gain in weight of 8 pounds (3.6 Kg.). The patient was bedridden but without symptoms except for pain in the upper part of the back left side of the neck and the suboccipital region for one-half hour daily. Blue spots were noted daily and two episodes of blurred vision. The menses had not returned. There was optic atrophy of the right disk.

Improvement continued. By October 22, four months after the last operation, she had gained 21 pounds (9.5 Kg.) and weighed 127 pounds (57.6 Kg.). The basal metabolic rate was -23. The visual fields, however, in November showed marked impingement of the left temporal field of vision and no light perception on the right.

Fourth Admission to Presbyterian Hospital (from Dec. 6 to 23, 1938).—This admission was arranged to check again the status of the patient in view of her improvement. She now complained that the previously noted left suboccipital pain was steady throughout the day, worse on awakening.

Physical examination revealed the same conditions as before with the same striking pallor. There was a definite gain in weight, so much so that the patient now looked slightly overweight. The blood pressure was 100 systolic, 70 diastolic.

X-ray films of the skull (fig. 2) and of the orbit (fig. 4) were interpreted by Drs. Dyke, Swenson and Ball as indicating growth of the aneurysm, despite the ligation of both common carotid arteries. The aneurysm was noted to be eroding into the sphenoid sinuses. The likelihood of infection or rupture from this development made further attack on the aneurysm imperative. Electrothermic coagulation of the aneurysm by the introduction of a wire into the lumen of the aneurysm was proposed. In view of the decided degree of hypophyseal insufficiency, it was felt that the patient would not be able to stand the trauma of a craniotomy. It was decided to insert the wire into the aneurysm through the orbital defect on the right. The patient went home for three weeks, to return for this procedure.

Fifth Admission to the Presbyterian Hospital (from Jan. 20 to March 11, 1939).—Jan. 21, 1939, two years and nine months after the first symptom, wiring of the aneurysm was carried out by Dr. Blakemore and the procedure on the eye by Dr.

W. P. McGuire of the Institute of Ophthalmology. The technic follows that described previously.¹⁰ The operative note follows: Under procaine hydrochloride anesthesia an incision was made through the lateral canthus of the right eye. Anesthetic solution was introduced into the orbital tissues. The eye was displaced medially. This gave access to the aneurysm, which had eroded the posterior orbit. Thirty feet of No. 34 gage coin silver enameled wire was introduced into the aneurysm through a special needle. The velocity of blood flow through the aneurysm was measured and found to be low. The wire was heated to an average temperature of 80 C. for a total of forty seconds. The aneurysm no longer bled when the needle was cleared at the conclusion of the operation.

Following operation there was progressive diminution of the vision of the left eye. One week after operation the pupil became fixed in dilatation with amblyopia and loss of the pupillary reflex. The fundus was negative at first but optic atrophy soon supervened. Other complications were the development of mild dehydration in the second week and in the third week the siting suturing of the right eyelid by Dr. McGuire, a pro-appearance of a pinpoint corneal perforation on the right, neces-

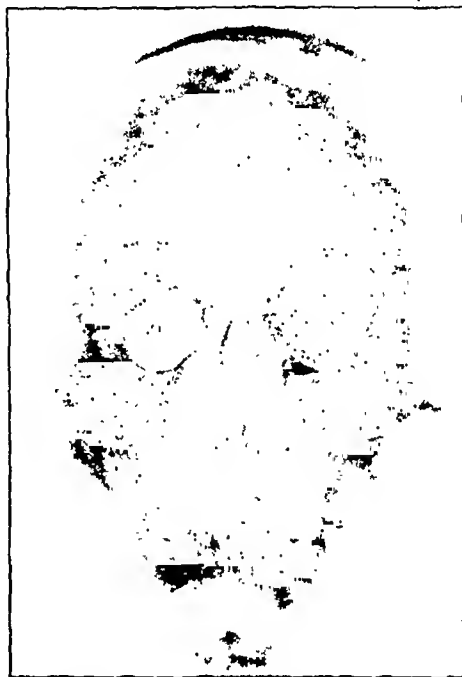

Fig. 5.—Anteroposterior view of skull, April 13, 1939, showing relation of aneurysms to defect in posterior wall of right orbit.

cedure which proved successful in combating the threatened infection. The patient was discharged three months after operation weighing 115 pounds (52 Kg.), but she was readmitted one month after this because of the severity of pain in the left suboccipital area of the neck and shoulder.

Sixth Admission to the Presbyterian Hospital (from April 10 to 28, 1939).—The right eyelids were well closed and the condition of the eye was satisfactory. The left fundus showed atrophy of the nerve head with small shrunken arteries. X-ray examination of the skull (Dr. H. H. Kasabach) revealed some further destruction of the posterior clinoid processes. X-ray examination of the cervical spine showed no dilatation of the vertebral canals to account for the pain.

On laboratory examination the basal metabolic rate was -31 and the fasting serum cholesterol was 209 mg. per hundred cubic centimeters.

Procaine hydrochloride and two days later benzyl alcohol 10 per cent were injected into the spinal dorsal ganglions of the second, third and fourth cervical vertebrae, with relief of pain. The second injection was followed by a hysterical episode that lasted two days. It was noted that for four days after the operation the left side of the face to the midline was flushed

in contrast to the previous marked pallor; skin temperatures, as the flush was subsiding, were equal on the right and left, however. Suboccipital pain was relieved by the injections made into the dorsal ganglions.

Seventh Admission to the Presbyterian Hospital (from June 6 to 13, 1939).—This admission was necessitated by a cellulitis of the right side of the face and neck following extraction of two lower molars a week before. Recovery was uneventful.

July 8, six months after wiring of the aneurysm, x-ray examination of the skull showed no further change (fig. 3).

Eighth Admission to the Presbyterian Hospital (from Oct. 22 to 31, 1939).—This admission was arranged to check the patient's progress. She was now out of bed from one-half to one hour every day, though glad to remain in bed the rest of the day. She had learned braille and was mentally alert, interested and in good spirits. Her appetite was described as poor by the family. The menses had still not returned. There was no nausea or vomiting. Physical examination was unchanged.

X-ray examination of the skull (Dr. Dyke) showed no advance of the area of bone destruction since April, six months before (figs. 3 and 5). The basal metabolic rate was -28 . The dextrose tolerance test fasting was 102 mg. per hundred cubic centimeters, one-half hour 143 mg., one hour 124 mg., two hours 105 mg. and three hours 100 mg.

A program of increasing activity was outlined and the patient was urged to get out of bed more and more. During her stay a tooth was pulled without complication.

Oct. 15, 1940, twenty-two months after the wiring, the patient weighed 140 pounds (63.5 Kg.), was ambulatory and relatively improved except for pain in the left eye occasionally. Amenorrhea persisted.

COMMENT

An aneurysm of the internal carotid artery within the skull was treated by wiring and electrothermic coagulation according to the method of Blakemore and King. The aneurysm was progressive despite ligation of both common carotid arteries. The situation was further complicated by the syndrome of Simmonds' cachexia due to destruction of the anterior hypophysis within the sella by the aneurysm. To date the patient has survived twenty-two months since the wiring, although the area of destruction from the aneurysm, at that time and now, measures roughly about 6 by 6 by 7 cm. Progression of the area of destruction has not occurred in the past sixteen months.

Before the wiring procedure, blindness with optic atrophy was present on the right. There was also blurring of vision and a diminution of the temporal field of vision of the left eye. Following the operation the remaining vision was lost on the left with subsequent optic atrophy. Pressure on the optic nerve following an increase in the size of the wall of the aneurysm from postoperative edema could account for this result. Swelling has been observed to occur in the walls of aortic aneurysms so treated. If this interpretation is correct, the edema might well have been avoided with two precautions. First, an x-ray film taken during the procedure, after the insertion of 2 feet of wire, would have outlined the active portion of the aneurysm. This would have afforded a more accurate guide for determining the amount of wire to be introduced than the estimate made from the area of bone destruction. Thus, the introduction of so much (30 feet) wire would have been prevented. Second, heating the wire to 70 C. for a few seconds is enough to deposit a protein coagulum on the wire adequate for clotting but with the production of less edema than after a temperature of 80 C. for forty seconds.

The possibility that propagation of the thrombus established within the lumen of the artery may have

accounted for the loss of vision cannot be ruled out. However, such a mishap has not followed wiring of any aneurysm of the aorta that has been so treated.

The wire was introduced into the aneurysm through the bony defect in the orbit because of the advanced degree of hypophyseal insufficiency. Any extensive surgical procedure, such as craniotomy, is ruled out in these cases by the overwhelming probability that shock will result from the least trauma. However, when the aneurysm has not caused hypophyseal destruction, craniotomy and insertion of the wire under direct vision is naturally to be preferred.

To date, the syndrome of destruction of the anterior hypophysis has not been much alleviated in this case. The enormous size of the aneurysm makes the possibility small that there is much surviving hypophyseal tissue or that there will be much decrease in the pressure in the sella. The ineffectiveness of substitution therapy by thyroid, adrenal cortex extract or anterior hypophyseal growth extracts should be noted. The toxicity of hypophyseal extracts when nearing adequate dosage and the ease with which hyperthyroid symptoms can be produced by thyroid should be stressed. Of incidental interest also is the appearance of flushing of the face following injection of the dorsal ganglions of the second, third and fourth cervical vertebrae. This would indicate that the marked pallor, first described by Simmonds and not due to anemia, is vasospastic in origin.

The procedure of wiring and electrothermic coagulation was applied in the treatment of an aneurysm of the internal carotid artery within the skull. The patient has survived since, fourteen months to date. This case is too complicated, because of the previous internal carotid artery ligation and the presence of advanced hypophyseal insufficiency, to judge the merits of wiring as a method of treatment of this type of aneurysm. Nonetheless, the operation has been accomplished successfully under these most adverse circumstances. This procedure is therefore presented to encourage its trial as a new, simple and probably effective operative approach to the treatment of aneurysms of the internal carotid artery.

SUMMARY

1. The wiring procedure of Blakemore and King for the treatment of aneurysms of the aorta has been extended to the treatment of aneurysm of the internal carotid artery within the skull.

2. An aneurysm of the right internal carotid artery within the skull, progressive despite ligation of both common carotid arteries and complicated by Simmonds' cachexia, has been successfully treated by wiring.

3. The pallor of the face associated with the syndrome of Simmonds' cachexia would seem to be vasospastic in origin.

4. Substitution therapy in Simmonds' disease is ineffective at present.

620 West 168th Street.

Tuberculosis Reactors Decrease.—In a ten year tuberculin testing program in rural and town schools in four counties in Minnesota the percentage of reactors has fallen from 14.1 to 6.75. The decrease is attributed to a careful follow-up of all positive reactors, with an intensive search for the source of the infection. Contact with open cases of tuberculosis was broken by hospitalization of the case or placing the children in a home free from tuberculosis. All teachers and school personnel were included in the plan.—National Tuberculosis Association Clip Sheet, February 1941.

THE INTESTINE IN RADIATION
SICKNESSI. THE GROSS EFFECT ON THE SMALL INTESTINE
OF PROTRACTED DEEP PELVIC IRRADIATION

WILLIAM STUART WALLACE, M.D.

DURHAM, N. C.

As the colon has frequently been studied with the intention of finding the cause of the diarrhea seen in radiation sickness and the findings have been inconclusive, and as diarrhea has been shown to be frequently due to disease of the small intestine,¹ I decided to investigate grossly the small intestine of a series of patients receiving heavy, long-protracted doses of high voltage roentgen therapy over the pelvis, using portals large enough so that there is direct irradiation of a portion of the small intestine.

LITERATURE

Several workers, notably Warren and Whipple² and Martin and Rogers,³ have overirradiated the abdomen in experimental animals and studied the pathologic change produced in the bowel. This work has given physicians a background of knowledge of the nature of the radiation injury, but unfortunately integration between it and the effects of therapeutic doses in man is practically impossible because of variations in susceptibility and the fact that, in treatment of the human patient, one endeavors to stop short of the damaging dose.

In such pathologic studies of the injured human bowel as have been made by Corscaden, Kasabach and Lenz,⁴ Healy⁵ and Cathie,⁶ the injuries have been generally acknowledged to be manifestations of an idiosyncrasy to irradiation, or else manifestations of local overirradiation of an immobile loop of bowel, fixed in position by peritoneal adhesions or extension of a tumor. Patients showing actual intestinal damage after therapeutic doses of radiation are all rare enough to merit reporting. Obviously pathologic examination of the bowel in patients showing normal response to a series of radiation treatments is not justified to satisfy experimental curiosity, and another method of examination must be used.

The examination of the small intestine by the use of ingested opaque substances is, of necessity, gross and in no way approximates the accuracy of the pathologic study. It surely will, however, at some future date be possible at the time of laparotomy or necropsy after death from some intercurrent disease to obtain pathologic material showing the normal response of the bowel to a heavy series of therapeutic radiation treatments. According to Martin and Rogers⁷ and Desjar-

dins⁸ the reaction of radiation sickness is nonspecific and differs widely from the specific reaction seen in the grossly overirradiated bowel.

The pathologic changes⁹ in the overirradiated bowel are:

1. Increased tone with spastic contraction.
2. Mucoïd degeneration, vacuolization and desquamation of the epithelial cells, beginning in the cells overlying the lymph follicles and lining the crypts and later extending into the cells covering the villi.
3. Atrophy of the villi.
4. Hyperemia and edema.
5. Occasional mucosal ulceration.
6. Bacterial accumulation on the denuded surfaces.
7. Infiltration of leukocytes.
8. Ultimate mucosal regeneration or proliferation of connective tissue to replace the destroyed cells.

Martin and Rogers³ have shown that a certain extent of these changes is entirely compatible with life, and it may be that radiation sickness is a manifestation of these changes in a mild degree. Warren and Whipple¹⁰ have shown that no overwhelming bacterial invasion occurs even with widespread ulceration, which seems to indicate that the symptoms of radiation sickness are

Characteristic appearance of intestine after barium sulfate meal.

not due to passage of massive numbers of bacteria through an injured mucosa of increased permeability. It is not the purpose of this paper to discuss the etiology of radiation sickness, or actual intestinal injury, as there are numerous hypotheses, none of which is conclusive, including the liberation of toxic products from irradiated lymphoid tissue,¹¹ actual metabolic changes,¹² the psychic element, the production of ozone in the treatment room and the release of a histamine-like substance from irradiated tissues,¹³ to mention only a few.

SELECTION OF CLINICAL MATERIAL

For a time, all new patients with carcinoma of the cervix coming under my care at the clinic of Duke Hospital were subjected to a preliminary study of the

small intestine before the institution of therapy. From these were selected 10 patients, in whom careful study had revealed no organic lesion of the gastrointestinal tract. These received the usual dose of radiation (with slight individual variations for physical condition of the patient and stage of the disease), and the small intestine was reexamined at the end of a protracted series of radiation treatments. None of these patients had received any radium therapy previously.

TECHNIC OF IRRADIATION

The 10 patients selected all received between 1,700 and 2,200 roentgens from each of two anterior, two posterior and two lateral portals, all 10 by 15 cm. With two exceptions, the rays were generated at 400 kilovolts, and 5 milliamperes, filtration of 4 mm. of copper, with a half value layer of 5 mm. of copper being used. In the 2 remaining cases, the rays were produced at 200 kilovolts and 25 milliamperes, with filtration of 1 mm. of copper, and a half value layer of 2 mm. of copper. In addition, 3 of the patients received around 5,000 roentgens intravaginally, with 500 roentgen doses interspaced after every third external treatment, the rays produced at 200 kilovolts and 25 milliamperes, with filtration of 1 mm. of copper and a half value layer of 2 mm. of copper.

In every case the external irradiation was given as follows, in a modification of the method used by Healy at Memorial Hospital:

1. Each day two opposing portals are treated, the rays always being directed exactly at right angles to the plane of the body parallel to the top of the treatment couch.
2. The anterior and the posterior portals on each side meet in the midline of the body, and no attempt is made to incline the beam and cross fire the cervix.
3. Each of the first three days, each of two opposing portals receives 150 roentgens.
4. Each of the second three days, each of two opposing portals receives 200 roentgens.
5. Each of the third three days, each of two opposing portals receives 250 roentgens.
6. Daily thereafter each of two opposing portals is given 300 roentgens until the desired total dose has been administered. (For economic reasons, the daily dose has been increased to 350 and even 400 roentgens per portal in a number of cases without undue effect, but the usual routine is to continue at 300 roentgens per portal until the desired total dose is reached.)

The patients, equally divided among white persons and Negroes, were all of farming families, and all withstood their irradiation without undue discomfort. No drugs were prescribed to alleviate any symptoms of radiation sickness which appeared, and in only 1 case did the diarrhea approach moderate severity, with three stools a day. (I recognize that nausea is likely to be a more prominent feature among a more exacting group of patients. However, this same general routine is followed at Duke Hospital in the treatment of every patient with carcinoma of the cervix, and no patient has yet shown any lasting injury, and in no case has the radiation sickness been of sufficient severity to cause more than temporary interruption of therapy. This intensive method of therapy is aimed primarily at eradication of the more radioresistant metastases to broad ligaments, in the belief that intracervical radium and intravaginal roentgen irradiation are highly effective in destroying the primary tumor in the cervix.)

TECHNIC OF EXAMINATION OF THE SMALL INTESTINE

It has been shown by several workers, Golden,¹ Menville and Ané,¹⁴ Pendergrass and his associates,¹⁵ that in examination of the small intestine the use of a standard meal and a standard technic of examination is necessary to afford a valuable comparison. Accordingly, none of these patients had any chronic medication of any type. To forestall any possible effect on the bowel from carbohydrate, fat, or flavoring materials, I used 3 ounces (85 Gm.) of barium sulfate¹⁶ in 6 ounces of water, which the patient was instructed to swallow rapidly. The esophagus and stomach were examined fluoroscopically at the time of the meal. The patient was allowed to sit for a fifteen minute interval, after which she was examined roentgenoscopically in the prone and supine positions and a roentgenogram was taken in the supine position, to show the duodeno-jejunal juncture and the upper jejunum, according to the technic of Golden.¹⁷ Good quality roentgenograms were obtained in the average patient with 90 kilovolts, 100 milliamperes and one-fourth second exposure, the Bucky diaphragm being used at a distance of 25 inches.

At hourly intervals after the meal, the patients were again examined with the fluoroscope in supine and prone positions, and roentgenograms of the prone patients, centered over the filled area of bowel, were made, the same technical factors mentioned previously being used. In every patient studied in this investigation at the time of the first examination the meal had reached the ileocecal valve and started into the cecum by the end of two hours. Accordingly in the majority of cases the examination was not continued beyond the end of the two hour period.

NORMAL APPEARANCE OF THE SMALL INTESTINE

The appearance of the various segments of small intestine in every case selected for complete investigation was essentially the normal one that has been well described by previous workers, including Forsell,¹⁸ Golden¹ and Pendergrass and his associates,¹⁵ and will be mentioned only briefly.

The duodenum showed a characteristic "fish bone" appearance, with high and fairly wide mucosal folds. Its lumen is from 3 to 4 cm. in diameter.

The upper jejunum showed a slightly narrower lumen, with much finer but equally high folds, producing the characteristic "feathery" appearance. As the meal proceeded to the lower jejunum, the folds gradually became slightly lower and wider and there was slight further narrowing of the lumen.

The characteristic appearance of the ileum shows a lumen well under 3 cm. in diameter, with folds not over a millimeter or two high and almost a centimeter wide. In some phases of peristalsis the ileum assumes the "stacked coin" appearance, with folds as narrow as those of the duodenum but not nearly as high, and frequently it shows longitudinal striations.

In normal persons the barium has a tendency to remain in a continuous stream, with only occasional empty segments interrupting the continuity, these due to recent peristaltic contraction.

In the duodenum and jejunum peristaltic contractions are massive, usually involving a segment 5 to 10 cm. in length. In the ileum the areas of peristalsis are much less extensive, and each wave usually involves only about 1 cm. of the bowel.

POSTRADIATION CHANGES IN THE SMALL INTESTINE

The findings in the studies of the small intestine made at the end of the protracted series of therapy are graphically illustrated in the accompanying table. In no case was there any demonstrable change in the duodenum or jejunum, both of which lay almost entirely outside the irradiated areas. The two most common changes were segmentation of the barium stream and flattening of the pattern of the ileal mucosa. Segmentation was

Early in this investigation, I conceived the opinion that the syndrome of radiation sickness might be due to a failure of the impaired mucosa to absorb food materials, with the production of an actual deficiency state, but this does not seem to be true when therapeutic doses of radiation are used. The findings in the small intestine in the common deficiency states tropical and nontropical sprue, have been ably described by Golden¹ and Snell, Camp and Watkins¹⁹ and by Golden¹ and Mackie, Pound, Miller and Rhoads,²⁰ and are in many ways similar to, though more extensive than, the changes herein described. In both of these deficiency diseases, segmentation of the barium stream and hypomotility of the small intestine are prominent features. However, the acute mucosal changes are observed more commonly in the duodenum and the jejunum than in the ileum, although there is the same loss of pattern and flattening of the mucosal folds seen in my cases. The mucosal change in the bowel of patients with deficiency diseases

Effects of Radiation Therapy: Clinical Summary

No.	Age	Race	Para	L. of N. Stage	Therapy (G External Ports)	Previous Gastro-intestinal Symptoms	First Ileal Study	After Therapy		Changes in Small Intestine After Therapy				
								Nausea	Diarrhea	Duodenum	Jejunum	Ileum	Segmentation	Diminished Motility
1	57	N	0	IV Adeno.	2,150 r/port 400 KV, 4 mm. Cu 4,500 r vaginal 200 KV, 1 mm. Cu	0	Negative	+	0	0	0	Narrowing, flattening of pattern	+	+
2	31	W	I	II Sq.	2,000 r/port 400 KV, 4 mm. Cu 5,000 r vaginal 200 KV, 1 mm. Cu	0	Negative	+	0	0	0	Narrowing, flattening of pattern	+	0
3	58	W	vii	III Sq.	2,000 r/port 400 KV, 4 mm. Cu	0	Negative	+	+	0	0	Narrowing, flattening of pattern	+	+
4	39	N	i	II Sq.	1,800 r/port 400 KV, 4 mm. Cu	0	Negative	0	0	0	0	0	+	0

6	40	W	iii	III Sq.	1,700 r/port 200 KV, 1 mm. Cu	0	Negative	+	0	0	0	Narrowing, flattening of pattern	+	0
7	66	W	xi	III Sq.	2,000 r/port 200 KV, 1 mm. Cu	0	Negative	+	0	0	0	Narrowing, slight flattening	+	+++
8	35	N	vi	IV Sq.	2,000 r/port 400 KV, 4 mm. Cu 5,000 r vaginal 200 KV, 1 mm. Cu	0	Decided hypermotility	0	0	0	0	Flattening	++	++++
9	60	N	iv	IV Sq.	2,000 r/port 400 KV, 4 mm. Cu	0	Negative	+	0	0	0	Narrowing	+	+
10	39	N	v	III Sq.	2,100 r/port 400 KV, 4 mm. Cu	0	Negative	+	0	0	0	Loss of pattern	0	+

observed in all but 1 case and changes in pattern, varying from a slight to a marked degree, were found in 8 of the 10 cases. A decrease in motility was shown in seven instances, and an absolute diminution in the diameter of the ileal lumen due to spastic contraction was shown in an equal number.

There was no apparent quantitative variation in effect obtained by slightly more than 20 per cent variation in dosage, by the use of 200 kilovolts and 1 mm. of copper as compared to 400 kilovolts and 4 mm. of copper, or by the supplementary use of a heavy dose of intravaginal irradiation at 200 kilovolts and 1 mm. of copper.

COMMENT

In the light of this study, it appears that the diarrhea from deep pelvic irradiation is due to changes in the large rather than in the small intestine, as all demonstrable change in the small intestine would tend to produce an opposite effect. This would not necessarily hold true in the case of irradiation heavy enough to produce permanent damage to the small intestine.

has been considered²¹ to be due to edema, going on to actual atrophy and destruction, though cases have been described¹⁶ which show no edema but round cell infiltration of the submucosa. It is highly likely that edema is the cause of the mucosal change in the 10 cases described previously. Finally, the patient with the true deficiency state frequently²² presents stubborn colitis, which was not seen in this series of cases even after tremendous doses of irradiation.

Further investigation of the length of time required for the small intestine to return to a normal appearance, the effect of sickness-producing doses of radiation

The operations to be considered in this appraisal are subtotal or total gastrectomy and resections of the small and large intestines. The conditions for which they are done necessarily influence the evaluation of results, inasmuch as surgical intervention for cancer where no medical treatment has efficacy may be regarded as justifiable to prolong life even on a less than normally comfortable basis. Recurrence of the disease is anticipated, and the surgical removal of the original lesion is intended as a day to day measure, justified by the patient's right and desire to live as long as possible. Likewise, a destructive disease such as ulcerative colitis is often so desperate that radical surgical intervention or colectomy, even with imperfect results, may be regarded as justifiable and desirable. In this disease, however, the internist is confronted with two tormenting factors: first, that with the uncertain and probably complex etiology a simple medical cause may be overlooked and an important organ unnecessarily sacrificed, and second, that this sacrifice may be unnecessary because of that apparently spontaneous improvement which occasionally occurs in this disease just as radical surgical intervention is being considered. Under these conditions necessarily imperfect results, while justified in desperate circumstances, should be avoided as long as the road between fatality and medical cure does not become too precarious. Peptic ulcer, on the other hand, is a disease which, when uncomplicated or even with the milder complications, should be amenable to medical treatment, and radical surgical intervention for this disease, even if productive of good results, should be done only with impelling indications. This fact is, of course, now widely acknowledged, and differing policies by various persons and groups are the results of differences in the appraisal of indications and results. For this reason, especially in this disease, frequent estimates of indications and results are an important practical help toward better therapy and even toward a clearer understanding of the etiology of the disease. In this review, an unselected group representing each type of case requiring radical surgical intervention was used.

The mortality of radical surgical intervention, while obviously the most important consideration in a discussion of results of treatment, has so often been discussed in relation to radical gastrointestinal operations that it will not be considered in this paper. This discussion concerns the living patient who has had resection, and attempts to cover two questions: (1) Has the operation relieved the condition for which it was done, and (2) is the patient gastrointestinally comfortable?

Two hundred and sixty-two patients were studied, 120 of whom had had resection of the stomach, 22 resection of the small intestine and 120 resection of the large intestine.

Resection of the stomach was done in these 120 patients for three conditions: in 91 for peptic ulcer, in 25 for carcinoma and in 4 for benign lesions not ulcer.

The results of radical operations for peptic ulcer will be considered first. Resection in this disease was done for three reasons: (1) intractability, (2) multiple hemorrhages and (3) obstruction unrelievable by medical management.

There were 49 cases of intractable ulcer—20 of duodenal, 17 of gastric and 12 of gastrojejunal ulcer.

In most instances of these intractable duodenal ulcers it was assumed after laparotomy that the ulcer failed to respond because of its anatomic location on the posterior wall of the duodenum and penetrating into the head of the pancreas. In some of these cases it was impossible surgically to remove the lesion itself. The 19 patients with gastric ulcer had resection chiefly because there was a reasonable suspicion of future malignancy because of recurrence, or of present malignancy because of failure to heal. The gastrojejunal ulcers, mostly jejunal, occurred a few months to many years after posterior gastroenterostomy and, like the duodenal ulcers, were thought to have resisted medical treatment because of their location and to be a menace because of the danger of gastrojejunal fistula, which in 2 cases had already actually developed.

The commonest symptoms suggestive of functional derangement after gastric resection are a sensation of fulness, sometimes to the point of nausea, regurgitation or vomiting directly after eating, loss of appetite and a general sensation of distention and distress throughout the abdomen. There is occasional diarrhea. When a definite jejunitis or new ulcer has occurred, the symptoms are typical ulcer symptoms. Of the 20 patients whose duodenal ulcers were resected, 8 were symptomless one to ten years postoperatively, while 13 patients had discomfort ranging from postprandial distention to vomiting and diarrhea, and in 5 of these jejunitis or jejunal ulcer was suggested both clinically and by roentgen examination. In none of these cases was free hydrochloric acid found after a test meal, but its absence without fluoroscopic control of the position of the tube in the resected stomach is not absolute evidence of a lack of secretion.

The 17 patients with intractable gastric ulcers who had resection are, up to now, much more satisfactory from the standpoint of good results. Eleven were found to have no digestive symptoms, while 6 had mild indigestion, in most cases ascribed to careless diet. None of these patients was known to have free hydrochloric acid after operation. It must be noted that while the ulcers of these patients are classified as intractable, the majority of them were resected because the complete healing of the ulcer had not occurred quickly enough to allay suspicion of malignancy. Their benign character as proved microscopically suggests that at least some of them might ultimately have healed, even if no operation had been done.

Of the 12 patients with intractable gastrojejunal ulcer who had lysis of the gastroenterostomy and subtotal resection, 4 were found to be symptomless one to ten years postoperatively; in the other 8 there had developed in one to nine years after resection symptoms varying from mild abdominal distress and distention to typical ulcer distress. Two had hemorrhages, one and four years respectively after resection, although no hemorrhage had occurred from the original ulcer. One had a second subtotal gastrectomy with excision of a second gastrojejunal ulcer, and 2 had successful medical treatment for what were thought to be recurrent gastrojejunal ulcers. Free acid, after test meals, in the gastric juice of 4 of these patients with recurrent ulcer was 12, 18, 26 and 28.

While the groups of cases just described are too small to permit of definite conclusions, it is rather striking that the surgical treatment of these ulcers follows the same pattern in the matter of end results as the medical

treatment. The gastrojejunal ulcers are the most resistant, the duodenal the next most difficult and the gastric the most satisfactory in results.

The second indication, multiple hemorrhages, was present in 41 cases: 29 of duodenal, 6 of gastrojejunal and 6 of gastric ulcers. Of this group, 6 patients had recurrent hemorrhages after subtotal gastrectomy (five original duodenal ulcers and one original gastrojejunal ulcer). In 4 of the 6 patients there was achlorhydria; the gastric juice of the other 2 showed a free hydrochloric acid content of 39 and 40 respectively. The first postoperative hemorrhage occurred in these patients one and a half to three years after subtotal gastrectomy. Eleven other patients had complaints one to four years later, ranging in severity from an uncomfortable fullness after meals to real ulcer distress. Three of these 11 patients had free hydrochloric acid, after a test meal, of 7, 12 and 79 respectively. The patient with an acid content of 79 had an acute perforation of a jejunal ulcer. The others had achlorhydria (without fluoroscopic control of the position of the tube). Twenty-three patients had no stomach consciousness, although 3 of these symptomless patients had free acid of 17, 20 and 45 respectively.

In this group of patients, on whom resection was done because of multiple hemorrhages, it is again noted those with gastrojejunal ulcer are the least satisfactory, 3 out of 6 having recurrent symptoms; in the duodenal group, 15 of 29 had postoperative symptoms, while the gastric ulcer group was 100 per cent satisfactory. It must again be emphasized, however, that all these groups are too small to allow definite deductions from these facts.

The third indication for resection was pyloric obstruction. There were 19 patients with obstruction, of whom 17 were entirely symptom free one to ten years after resection. Two patients had mild symptoms, but neither had recurrence of the ulcer. Five were known to have achlorhydria postoperatively, and 1 had a free acid content of 14. This group, therefore, showed an almost 100 per cent good result from subtotal gastrectomy. In discussion of this fact, it might be thought that for this indication a less radical operation, such as gastroenterostomy, might be just as effective as this radical procedure, but in my opinion this would not have been true, especially since 11 of these patients were under 50 years of age, with high gastric acidity.

To revert to the three criteria set up at the beginning of this paper, namely: (1) Does this operation, subtotal gastrectomy, cure the disease and why? (2) Is it the least radical procedure possible? (3) Is the cure worse than the disease? I would first again emphasize the fact that the total number of cases is too small to justify conclusions and that no group of statistics regarding ulcer can be considered final as long as the patients are alive. Under these conditions, while no conclusions may be drawn, comment and discussion of these results may be permitted. It is rather striking that hemorrhage and intractability in the duodenal and gastrojejunal ulcers are less easily controlled by subtotal resection than in the gastric ulcer. Since gastric acidity in patients with gastric ulcer is almost always within normal range and in those with duodenal and gastrojejunal ulcer high, it is tempting to assume that this factor plays an important part in postresection results. Even when no new ulcer occurs, it is possible that gastritis or jejunitis, probably associated with this

acid factor, produces new symptoms. Only in the individual case can it be determined whether these new symptoms are more unpleasant or serious than those for which operation was done, but if the possibility of previous medical treatment has been exhausted it becomes necessary to give the patient an opportunity for relief and safety with a surgical procedure. This opportunity may involve a relatively high chance of recurrence or some postoperative discomfort, but it must still be given the patient if everything else has failed. The good results in cases of obstruction may also be due to the fact that acid plays a less important role in these cases where the indication for operation has been the relief of the cicatricial end results of ulcer formation and not of the active ulcer.

The second question, "is it the least radical procedure possible for this condition?" is in my opinion to be answered in the affirmative. As time goes on and experience with ulcer accumulates, the number of patients on whom gastroenterostomy and pyloroplasty have been performed who return, often fifteen to twenty years after the operation, with that most distressing of all ulcers, the gastrojejunal, grows steadily larger. In a few patients with more insidious gastrojejunal ulcers there has already developed a jejunocolic fistula; a larger percentage of patients has hemorrhage or perforation—in fact the complications are more numerous than in the simple duodenal ulcer for which operation was done. The complete picture of cases of gastric resection is yet to be unfolded, but with reduction of acid in most cases it can hardly be as disappointing as that of gastroenterostomy.

The third criterion, "is the cure worse than the disease?" involves not only a consideration of the number of recurrences of ulcer after the operation, which has already been discussed, but also a survey of the general condition of those patients who have been relieved of their original disease by extirpation of a large part of what is usually considered an important organ, the stomach. Ivy has recently enumerated six functions of the stomach, the digestive, triturating, reservoir, hemopoietic, bactericidal and absorptive, the last especially for iron and calcium. With a large part of the stomach removed, the small intestine must take up the burden of these functions to a large degree in patients with gastric resection. If the stump of the stomach shows peristalsis and gradual emptying, the reservoir and triturating functions are maintained to a considerable degree, and if there is cooperation of the patient through the substitution of small meals at frequent intervals for infrequent large meals, the subjective symptoms of postprandial fullness and discomfort are avoided. The other functions of the stomach are less easily checked, but in the group of cases in which postoperative liver and iron therapy and careful nutrition were prescribed practically routinely, there appeared to be no serious disturbance in the hemopoietic or absorptive functions—which were likewise assumed to be taken over, at least to some degree, by the small intestine. In 27 of the 91 cases there was some difficulty in maintaining weight and in general no tendency to overweight.

Twenty-five patients who had had subtotal gastrectomy for carcinoma of the stomach, observed one to eleven years after operation, showed a surprising lack of symptoms until loss of appetite indicated metastatic

involvement. Instead of fulness and nausea, as observed in the cases of ulcer resection symptoms possibly suggestive of jejunitis—the only symptom noted was diarrhea. There was practically always a gain in weight before the onset of metastatic involvement. From these facts again it is suggested that the hyperchlorhydria factor absent in gastric ulcer and cancer and present in duodenal and gastrojejunal ulcer, where it may produce an inflammatory condition or new ulcer in the newly invaded jejunum, is still the element incompletely controlled even by this radical operation.

In 1 case, total gastrectomy was performed in October 1937 for leiomyosarcoma. The patient is well, maintains her weight and has had practically no discomfort since the operation.

Of the 4 patients who had had resection of the stomach for benign lesions not ulcer, 1 had chronic hypertrophic gastritis, 1 a gastric diverticulum and 2 leiomyomas. Satisfactory results have been obtained since operation, and the patients have no discomfort.

Resections of the small intestine were done in 23 cases for the following diseases: malignant lesions, 4 cases; regional ileitis, 12; Meckel's diverticulum, 3, and chronic intestinal obstruction, 4. In many cases long segments of this organ were removed. On the whole, there was remarkably little apparent effect on digestive function. Of the 4 patients whose small intestine was resected for malignant ulcers, 2 are entirely symptom free six and eleven years respectively after operation; their nutrition is maintained above normal, and they have had no recurrence. The other 2 have had one and a half and four years respectively of comfortable living but are now beginning to show evidence of recurrence. While the small intestine was intact, even though shortened to a considerable degree, there appeared to be no impairment of function. This fact was also true in 8 of the 12 cases of regional ileitis; these patients obviously enjoyed perfect health after the removal of the diseased segment of intestine which, while it was still present in its diseased form, caused symptoms of toxicity and obstruction severe enough to require surgical intervention. The other four of the twelve patients with regional ileitis had minor postoperative disturbances, 3 having some distention (general abdominal or in the right lower quadrant) and 1 having diarrhea. The three patients on whom resection for Meckel's diverticulum was done were in excellent condition postoperatively. Of the 4 patients operated on for chronic intestinal obstruction, 3 had postoperative symptoms, 1 having been reoperated on and the other 2 having recurrence of pain presumably due to the same mechanical and extrinsic cause, adhesions, for which the operation had to be done originally. One was well and had gained 20 pounds (9.1 Kg.).

In summarizing the clinical impressions of patients who have had resection of the small intestine, it seems apparent that large segments of this organ can be removed without disturbance of its function.

The patients with resections of the colon studied for this paper numbered 120, and the indications were as follows: carcinoma of the right portion of the colon, 25; of the left portion of the colon, 28; of the sigmoid flexure and rectum, 48; ulcerative colitis (colectomy) 15, and diverticulitis (resection), 4.

A large number of these patients were confronted with the inconvenience and handicap (mental and physi-

cal) of a permanent artificial abdominal opening. As was to be expected, the physical difficulties of an ileostomy, as in the colectomy cases, resulted in much greater disturbances than were present in the colostomy cases. The mental effects were usually in proportion to the physical, though in some instances related only to the person's temperament. Even the ileostomy was satisfactorily controlled, however, in 11 of the 15 patients operated on for ulcerative colitis, and in all patients but 1 there was an increase in weight which in most instances had to be controlled by a careful dietary regimen. The rescue of such patients from a desperate condition seemed, even to a critical reviewer, a justifiable reason for the radical operation, and when it is further observed that there is also a decided increase in nutrition and a return to full capacity in 11 of these 15 cases, even the most conservative internist must agree that the operation should be done in the desperate cases when there is destruction and polypoid degeneration of the mucosal surface and infiltration of the submucosal layers, or when the toxicity is so profound that recovery appears impossible. There will always remain the important question as to when this state supervenes on that doubtful one where cure by medical treatment may be obtained.

The colon resections done for malignant lesions, whether of the right or left portion of the colon or rectosigmoid, appeared to be entirely justified by the results, if these results are judged by the aforementioned criteria 2 and 3. In other words, cure of the disease is not expected, but physiologic function was adequate and the temporary cure was justified by the comfort of the patients. Twenty-two of the 25 patients who had had resection for lesions of the right portion of the colon showed, in one to six years postoperatively, full capacity for work. There were no digestive disturbances and no anemia, and the only nutritional disturbance was a striking tendency to overweight which predominated in all patients with radical operations of the colon. This fact may be ascribed to the type of diet used by them to reduce the liquid of the intestinal content, which seems more probable as a cause of this tendency to obesity than any possible biochemical or glandular factor resulting from the operation. The 28 patients who had resection for malignant lesions of the left portion of the colon showed, in twenty-six instances, excellent results in one to ten years after operation, good digestive function and full capacity. Here, too, there was no nutritional disturbance except difficulty in keeping the weight down to normal. One patient had nutritional anemia and 1 a postoperative surgical complication.

The 48 patients operated on for carcinoma of the sigmoid flexure and rectosigmoid had equally satisfactory results. During the period of postoperative observation, from one to eleven years, their nutritional condition was on the overnutrition side, they had good control of their colostomies and their capacity for work was normal.

Of the 4 patients with diverticulitis who had resection, 3 were satisfactory from all standpoints, and 1 continued to have some abdominal pain.

In summary, it may be concluded from this study of 262 patients who had radical surgical intervention done on the gastrointestinal tract that resection of any part of the digestive tract is entirely justified when the

lesion is malignant, and that until metastatic involvement occurs the patient may expect satisfactory function and capacity. In ulcerative lesions, both peptic ulcer and ulcerative colitis, radical surgical intervention is justified in cases which are really intractable, but because of the deforming operation in both cases and the possibility of recurrence of peptic ulcer, there should be the highest possible degree of certainty for the need of the operation. Furthermore, since in both diseases the etiology is still obscure and the probable real nature of the disease at least partly constitutional and remote from the locale of the organ itself, there is always the hope that a less radical etiologic treatment may be found to make radical surgical intervention unnecessary. In fact, this type of intervention, while indispensable at present, must still be regarded as far from the final answer to these problems. Of the three organs concerned in this study—the stomach, the small intestine and the colon—it is obvious that the small intestine is by far the most important from the standpoint of physiologic function, and furthermore that it is equipped to assume to some degree the function of both stomach and colon when these organs have been removed.

ABSTRACT OF DISCUSSION

DR. JOHN G. MATEER, Detroit: Our experience has been similar to that of Dr. Jordan. We also have advised operation on only the complicated or the intractable cases. At the Henry Ford Hospital, during the past two years, with further improvements in operative procedure and in preoperative and postoperative care, there has been a further reduction of the operative mortality for gastrectomy from 5 per cent to 2.5 per cent, or two deaths in the last 80 consecutive cases. This reduction of our mortality has encouraged Dr. McClure to substitute almost routinely partial gastrectomy for gastroenterostomy in the complicated ulcer cases. An analysis has been made of the therapeutic end results in the 50 cases of complicated peptic ulcer which have been followed carefully in our gastrointestinal clinic over a period of six months to seven years following gastrectomy. The end results in this total group of benign ulcers include the more and less favorable subgroups of pyloric obstruction, repeated hemorrhage, intractability of ulcer activity, jejunal ulcer and suspected malignant gastric ulcer. A variation in the percentage of patients in the different subgroups of ulcer complications operated on in different clinics necessarily produces some difference in the percentage of optimum therapeutic end results obtained. In 74 per cent of our total group the therapeutic end result was most gratifying, with practically no residual symptoms. In an additional 14 per cent the patients complained of some periodic epigastric fullness and flatulence (as referred to by Dr. Jordan); but the condition of these patients was greatly improved over their preoperative state. In 8 per cent of this total group jejunal ulcer developed after gastrectomy, and in three fourths of these jejunal ulcers hemorrhage developed after pain. The other 4 per cent of patients suffered a great deal of distress, although there was no evidence of postoperative ulcer. To obtain a low percentage of mortality and a high percentage of satisfactory end results from partial gastrectomy for complicated ulcer there are three essential requirements: (1) painstaking preoperative preparation of every patient, (2) operation by a skilful and experienced surgeon and (3) prolonged follow-up medical care of these patients. This care should emphasize continued proper habits of living and, temporarily, an adequate and comprehensive but concentrated diet with five small meals a day. In the few definitely intractable cases of chronic ulcerative colitis ileostomy alone is not always adequate, and subsequent colectomy may be a life-saving measure.

DR. HENRY L. BOCKUS, Philadelphia: Dr. Mateer and Dr. Jordan have mentioned that none of their patients went to the operating room until they had been thoroughly treated medically.

Only the intractable ulcers were subjected to surgery. Consequently the results in their cases are not quite so good as those reported in many of the European clinics where this operation is being done routinely for uncomplicated ulcer. Naturally, the mortality in foreign clinics will be less and their recurrences will be fewer, since many of their patients would have responded to adequate medical management. There are about 25 per cent of cases from the statistics of both Dr. Mateer and Dr. Jordan in which the results are not satisfactory. They include the retractable cases that do not do well with any type of treatment. I should like Dr. Jordan to tell us whether she thinks that these patients would be better off if they had not had a subtotal gastrectomy. Many gastroenterologists have the idea that resection of a considerable section of the small bowel leaves the patient in an unfavorable state of subnutritional equilibrium. It is surprising how much of the small bowel can be resected, for example in extensive regional ileitis, and still have the patient go along in a state of good nutritional equilibrium with some attention devoted to the supplying of nutritional elements. I have had one patient who has had about 6 feet of the small bowel resected and who is doing quite well with only two or three bowel movements a day. I should like to reiterate what Dr. Jordan has said, that it is quite important to consider surgery for all of these patients and not to feel that they are beyond the resectable stage if at least the upper half of their small bowel seems normal. I do not agree entirely with the author's remarks dealing with surgery in ulcerative colitis. Our mortality in ulcerative colitis seems definitely proportionate to the number of cases in which operation is performed. We lose very few cases if surgery is not employed. Many of the seriously ill patients, even when they have arrived at the stage when ileostomy was suggested to the family, may go into a remission when it is least expected—if intensive adequate therapy is persistently and doggedly used. For these reasons I have taken a more conservative attitude toward colectomy in the treatment of typical distal advanced ulcerative colitis.

DR. SARA M. JORDAN, Boston: The postoperative nutritional care and treatment with liver and iron, which is done routinely in our clinic, we feel, is most important for patients who have had subtotal gastrectomy. It undoubtedly helps in preventing later anemia; furthermore, the matter of nutrition was of interest in the study of the cases. Postoperatively, patients who have had gastrectomy showed a great tendency to be below their normal weight, while the patients who had resection of the colon and even resection of the small intestine had difficulty in restraining the gain in weight. This fact was an interesting commentary on the digestive processes but may possibly be due to the fact that the colectomy patients, of course, use a diet which is intended to produce formed stools and which probably is also more fattening. Dr. Bockus asked the question whether I felt that these patients were better off even if they did have postoperative trouble. There I think we again have to classify the cases. Those who have an intractable ulcer, e. g. the duodenal ulcer, intractable because it is on the posterior wall of the duodenum and penetrating into the pancreas, are definitely better off, I feel, if the intractability is due to symptoms which result from even mechanical or possibly chemical causes. Hemorrhage, however, still presents a real problem. A patient who has been operated on for multiple hemorrhages, and hemorrhages again after a subtotal gastrectomy, finds himself in a distressing situation, and I think the patient would have to answer the question for himself whether the postoperative hemorrhage which he has occasionally is better or worse than what he had before operation. The outlook in such a case is dubious as far as good results are concerned. With regard to colectomy for ulcerative colitis, I think it presents the most difficult question in gastroenterology: when surgical operation is called for in these desperate cases. Surgeons are really not anxious to operate on these patients because they, too, feel the responsibility of the situation. We try to treat them as long as we feel there is a chance of helping them medically. The two points I brought out are most important here: (1) the possibility of spontaneous remission or cure and (2) the possibility of a discovery tomorrow or the next day of a cause for ulcerative colitis which will make this radical surgery unnecessary.

Clinical Notes, Suggestions and New Instruments

AN EASILY CONSTRUCTED WANGENSTEEN SUCTION APPARATUS

E. E. MYERS, M.D., PHILIPPI, W. VA.

There is a definite need for an inexpensive, easy to operate, foolproof apparatus to provide suction of the Wangenstein type. The last two desiderata are provided by machines now obtainable from surgical supply houses, but the item of expense prevents most hospitals from possessing as many machines as they would like to have.

The accompanying illustration shows a suction apparatus inexpensive and easily constructed, simple in design and convenient in operation. This apparatus embodies a new principle, in that both bottles are kept in the inverted position, making the connections and operation simpler.

The construction, briefly described, is as follows: The stand is made from 1 inch (2.5 cm.) pipe and is 5½ feet (167.6 cm.)

The suction apparatus set up ready for use.

high; the base is 22 inches (55.8 cm.) wide. The center of the base employs a "cross with side outlet." The wheel at the top is a clothesline pulley, obtainable at most hardware stores. This is plated to a ¾ inch (1.9 cm.) pipe which, when threaded, tapers sufficiently to fit tightly into the 1 inch pipe. The support for the upper bottle is made from a piece of strap iron bent around the pipe stand, held with a bolt and wing nut and having a ¼ inch (0.64 cm.) soft iron bar welded to it. The lower support, which holds the tube from the collecting bottle, is made from strap iron having a hole in the end through which the tube from the collecting bottle is placed. A short piece of rubber tubing passes through the hole, which is barely larger than the tubing. Above is a Sim's nozzle and below a straight connecting tube. This arrangement keeps the tube in position.

In each bottle are two glass tubes; one goes the length of the bottle and the other just through the rubber stopper. The short tubes are connected together with a long piece of rubber tubing, and the long tube of the upper bottle is attached to the collecting bottle. In operation, when the upper bottle is empty the Sim's nozzle is disconnected from the short piece of rubber tubing attached to the upper bottle and the position of the bottles changed. This is easily done by pulling down on the one while the other is lifted. The Sim's nozzle is then connected to the rubber tube of the raised bottle, and suction is produced by the flow of water to the lower bottle. It is advisable to clamp off the tube from the collecting bottle during the change, in order to maintain suction.

A word of caution in the use of this apparatus: The support for the collecting tube is essential, because without it the bottles might be changed in position without disconnecting this tube and air forced back into the patient. Glass connecting tubes on either side of the support prevent the tube from sliding through the support, and as long as the apparatus is set up in the manner described there is no danger of this kind.

The holders for the bottles can be made from canvas, wire, metal bands or, as shown in this equipment, from rings and rope. Harness rings 1¼ inches (3.1 cm.) in diameter are used for support of the bottles on the horizontal bar. The rubber stoppers are held in the bottles by stout twine tied in the manner illustrated in an article by Wangenstein.¹ Sash cord is used over the pulley to support the bottles.

The instrument has this advantage, that the degree of negative pressure can be easily varied if desired by changing the position of the horizontal bar on the stand.

The cost for the materials used does not exceed \$5, and the entire apparatus should be made for less than \$10.

The Myers Clinic Hospital.

Special Article

GLANDULAR PHYSIOLOGY AND THERAPY

CORPUS LUTEUM HORMONE

GEORGE W. CORNER, M.D.

BALTIMORE

This special article is published under the auspices of the Council on Pharmacy and Chemistry. It is one of a series which will be published in book form as the second edition of "Glandular Physiology and Therapy." The opinions expressed in this article are those of the author and do not necessarily represent the views of the Council.—Ed.

FUNCTION OF THE CORPUS LUTEUM

Speaking broadly, the endocrine function of the corpus luteum is now well understood. The gland is a part of the mechanism of pregnancy. When an ovum begins its journey through the fallopian tube, the follicle from which it took origin gives place to the corpus luteum, and this organ thereupon delivers into the blood stream a substance, progesterone, that has the property of causing extensive development of the endometrium, preparing the uterus for the reception and nutrition of the embryo.

Action on the Uterine Mucosa.—The action of the corpus luteum on the uterus is best known in the rabbit, because that species especially has been used for experiments with progesterone. About two days after the formation of the corpora lutea or after the beginning of a course of treatment with progesterone, rapid cell division begins in the epithelium, resulting in a downgrowth of the glands and ultimately in branching so profuse that the endometrium is crowded full of glands. The cells of the surface epithelium also increase in number by mitotic division so that the surface is folded. The epithelial cells, both on the surface and in the glands, become taller and acquire a more definitely columnar arrangement, presenting finally the appearance of secretory activity.

Accompanying this intense wave of epithelial proliferation there is marked engorgement of the endometrial blood vessels. By the fifth day the cells no longer divide, presumably because they have been converted to the secretory state, and the progravid condition is well established.

Because the implantation of the embryo (which these changes serve to promote) differs considerably in

592

different animals, the progestational proliferation differs also in detail. In the domestic pig, for example, with its superficial and noninvasive placentation, it is only the surface epithelium of the uterine lining which comes into contact with the embryonic tissues; therefore the effect of the corpus luteum is chiefly on the surface cells.

In the human and the other primate species, on the contrary, the implantation is invasive, and the progestational proliferation consequently affects chiefly the glands and the stroma, producing the well known "premenstrual" endometrium, in which the glandular epithelial cells become very high, with frayed surfaces, and the glands are dilated and acquire serrated contours. Glycogen is deposited in the epithelium, and the connective tissue cells of the stroma begin to enlarge in preparation for decidual change if pregnancy ensues.

By the time the fertilized ovum reaches the uterus, the endometrium is therefore already in a state of heightened secretory activity, by which (presumably) nutritive substances are provided for the embryo. The nature of this favorable chemical action is not yet clearly known; the experiments of Pincus¹ suggest that glutathione is secreted into the uterus and stimulates growth of the early embryo and of the endometrium itself.

When the embryo, thus nourished by the secretory activity of the endometrium, goes on to the stage of implantation, its requirements are met by another response of the uterus under the influence of the corpus luteum. The endometrium in some way is sensitized so that it responds to the presence of the embryo by forming the maternal part of the placenta (and the decidua, in those species in which the endometrial stroma becomes deciduous). This effect is well seen in the guinea pig, in which Loeb showed long ago that even in the nonpregnant animal the presence of corpora lutea in the ovaries is sufficient to induce in the uterus a special state during which any mechanical irritation (such as the presence of a small foreign body or a scratch) will produce a mass of decidual tissue exactly as if the embryos had been there to call it forth by the stimulus of their implantation.

Experiments have amply shown that removal of the corpus luteum during the early part of pregnancy causes failure of implantation of the embryo; if the embryo is already implanted, removal of the corpus causes destruction of the pregnancy.

Conversely, extracts of the corpus luteum that are administered to animals castrated during early pregnancy are able to replace the missing secretion and to maintain pregnancy.

Action on Uterine Muscle.—In addition to its progestational effect on the uterine mucosa, progesterone acts also on the uterine muscle, diminishing its spontaneous contractions and thus rendering the uterus quiescent. This probably also serves to facilitate attachment of the embryo, by inhibiting movements of the uterine wall which might hamper implantation at the critical time when the embryo is settling down at its site of attachment.

Although this action of progesterone varies considerably in different species, there is good evidence that it occurs in the human species.² This is important

in connection with therapy, for it suggests the possibility that the substance may be useful not only for its specific effects on the endometrium but also for its sedative action on irritability of the myometrium.

So far as is known at present, the corpus luteum has no useful action except in pregnancy, but in most mammals (including the human species) the gland is formed in every cycle, in anticipation (so to speak) of pregnancy, and therefore in each human cycle the corpus luteum normally acts for about two weeks, bringing about the so-called premenstrual stages of the endometrium. When it retrogresses, menstruation ensues. Thus in the adult nonpregnant human female the corpus luteum is functioning about half the time, and takes part in the general physiology of the body to that extent. In animals with less frequent cycles the proportion of time during which the corpus luteum functions is much less; obviously, therefore, it is not necessary for general well-being.

PROGESTERONE

The substance elaborated by the corpus luteum which gives the effects described was first extracted in crude form from the ovaries of swine by Corner and Allen³ and by Hisaw, Meyer, Weichert and Fevold⁴ and was partially purified by Allen.⁵ Investigations by Butenandt and Westphal,⁶ by Slotta, Ruschig and Fels⁷ and by Allen and Wintersteiner,⁸ all of whom obtained the active factor in the pure state practically simultaneously, revealed that progesterone is a crystalline steroid having the formula $C_{21}H_{30}O_2$. It is closely related to the natural estrogens and androgens.

A number of other substances, closely related chemically to the ones just mentioned, have been found to have the same effect on the uterus as progesterone, but only in much larger doses. Pure progesterone exists in two different crystalline forms, one melting at 128 C. (α progesterone) and the other at 121 C. (β progesterone). It has been produced synthetically from the vegetable sterol known as stigmasterol; the material now on the market is presumably made by similar methods from this or another sterol. By general agreement of the investigators concerned, the name "progesterone" is used for the pure principle; the term "progestin" is used to indicate the whole group of substances having similar action and to describe such a factor when present in a partially purified state or when not fully identified chemically.

Progesterone is administered by intramuscular injection, in solution in a vegetable oil; it cannot be given by mouth, because either it is not absorbed from the gastrointestinal tract or it is inactivated by the processes of digestion. In 1939 pregnenolone, a substance

closely related to progesterone, was found to be effective when given by mouth.¹⁰ This drug is now available commercially, but at the time of writing little clinical experience with it has been reported.

In castrated rabbits progesterone readily produces progestational changes in the uterus; in rabbits castrated during early pregnancy it will protect the embryos by substituting for the product of their mother's corpora lutea and will maintain the pregnancy to full term. In guinea pigs it sensitizes the uterus to produce the maternal part of the placenta (Loeb's deciduoma).

In castrated women the premenstrual state of the endometrium can be produced by administering large doses of estrogen to bring the uterus back to its normal interval stage and then progesterone to effect the premenstrual changes. In monkeys progesterone has been shown to inhibit menstruation; but if a course of treatment with progesterone is given to the normal animal, or to a castrated animal suitably prepared with estrogen, menstruation inevitably follows discontinuance of the progesterone. Similar effects have been seen in human subjects.

International Unit; Assay.—In 1935 a conference under the auspices of the League of Nations adopted an international standard of potency, which was defined as the amount of progestational activity present in 1 mg. of progesterone. This international unit has been generally adopted. The assay is usually performed by administering the preparation to be tested for five days to an adult female rabbit that has been mated and then castrated, or to an immature rabbit of about 600 Gm. weight which has been primed with five to ten daily doses of estrogen preceding the course of treatment with the test preparation. The progestational effect on the endometrium is estimated microscopically from sections of the uterus. Before the League of Nations standard was set up, various investigators were making use of other units. The Corner-Allen unit, based on use of the adult rabbit for assay and commonly cited in the American literature, is approximately equal to the international unit; the Clauberg unit, based on the immature rabbit, represents about 0.6 international unit.

Pregnandiol.—Endocrinologists owe to Venning and Browne¹¹ the demonstration that pregnandiol, a substance chemically related to progesterone and already known to exist in the urine of pregnant women, is actually derived from progesterone and represents the latter's excretion product. Pregnandiol as it appears in the urine is conjugated with glycuronic acid to form a water-soluble compound, sodium pregnandiol glucuronide. Since each molecule of pregnandiol represents one molecule of progesterone, the amount of the former substance recovered from the urine in a given period gives at least a rough measure of the functional activity of the corpus luteum, although losses during excretion and during chemical manipulation, amounting perhaps to 50 per cent, prevent an exact measure of the progesterone output.

In the normal menstrual cycle pregnandiol appears in the urine about twelve days before the onset of menstruation (i. e., a day or two after ovulation). The excretion reaches a peak about one week before menstruation and usually ceases two or three days before the onset of bleeding. The curve of pregnandiol

excretion thus closely parallels the rise, activity and retrogression of the corpus luteum. From several investigations¹² one learns that the daily output at the peak, though variable, is of the order of 5 mg. of pregnandiol daily, and this may be conjectured to mean that the corpus luteum when most active produces something like 10 mg. of progesterone per day.

In pregnancy the output of pregnandiol begins to rise about the seventieth to the ninetieth day and in the ninth month may reach 60 to 100 mg. daily.¹³ It is generally agreed that the large amount of progesterone indicated by these figures is not made by the corpus luteum but by the placenta.

CLINICAL POSSIBILITIES

Progesterone is now available in the drug trade, and the price, though still high, has been reduced sufficiently to make its use possible. Progesterone therapy is still, however, in the stage of experiment, and all the physician can do at present is to follow with caution the lead of the more critical clinical investigators as they progress. The clues given by its known effects on the endometrium and myometrium have naturally suggested its use in recurrent and threatened abortion, in dysmenorrhea, in after-pains of the early puerperium and in so-called functional uterine bleeding.

Recurrent Abortion.—Since the corpus luteum, as already shown, plays an essential part in promoting the growth and implantation of the early embryo and is necessary for maintenance of pregnancy during its earlier period, it is obvious that failure of the corpus luteum may be at times the cause of abortion. Such a result might be due to failure either of the progestational ("premenstrual") secretory reaction of the endometrium or to nonoccurrence of the quiescent state of the endometrium induced by progesterone or to both. Evidence has been obtained by Browne, Henry and Venning^{13b} from estimations of pregnandiol excretion that in certain cases spontaneous abortion is indeed associated with diminished function of the corpus luteum. In such cases the condition should be relieved by treatment with progesterone. It is also possible that progesterone might be useful in preventing spontaneous abortion from other causes; by its property of inhibiting uterine motility it might act to reduce crampy uterine contractions no matter what their cause. There have been a number of favorable reports on progesterone therapy for recurrent abortion. Obviously, the results must be considered critically, for it is never possible to know in any individual case what would have happened without therapy. Statistical criteria for judging the results have recently been laid down by Malpas¹⁴ and by MacGregor and Stewart.¹⁵ Women who have aborted spontaneously three times are statistically almost certain to abort again if they become pregnant;

such patients afford a real test of therapeutic effects, and if pregnancy is maintained, it is probable that the treatment was useful. The latest investigators rather cautiously agree that progesterone is a valuable agent in such cases.¹⁶ Treatment should be begun as soon as pregnancy is suspected. Not less than 1 mg. daily is to be given, and preferably more, up to 5 or even 10 mg. If, as seems likely, the placenta supplies the hormone after about the third month, progesterone treatment is probably unnecessary thereafter.

Threatened Abortion.—It has been observed repeatedly that the cramps and bleeding which indicate a threatened abortion may subside after the injection of 1 mg. or more of progesterone, probably because this substance inhibits uterine motility and causes growth of the endometrial tissue. In such cases, if viability of the fetus is indicated by clinical signs and a urinary test for pregnancy (Aschheim-Zondek, Friedman) is positive, the patient should be put at rest and given progesterone in ample dosage (not less than 1 international unit daily, and if possible, 5 or even 10) until the symptoms subside. After this, 1 unit daily may be given until it is thought safe to let the patient get up; thereafter less frequent doses are probably indicated until late in pregnancy. If symptoms recur, more intensive treatment may be resumed.

The advice to use relatively large doses, given in the foregoing paragraphs, follows the trend of sound clinical and laboratory experience and agrees, moreover, with the known rate of normal secretion by the human corpus luteum (see foregoing section on pregnandiol; during the third month, the most critical period for abortion, the normal patient is probably producing 15 to 40 mg. of progesterone.) Clinical results from very small doses, representing fractions of 1 unit per day, have been reported. It is perhaps possible that such small doses may at times serve by a trigger-like action or by redressing a delicate imbalance, but in the present state of knowledge 1 mg. per day is surely the least quantity that could conceivably affect the human body. There has never been any report of harmful effects from progesterone, in animals or women, even with large doses.

Dysmenorrhea.—Investigators have no satisfactory and comprehensive explanation of the cause of primary dysmenorrhea, and in all probability the condition is not a single clinical entity. The use of progesterone has sometimes been based on special hypotheses about endocrine factors in dysmenorrhea and sometimes on the hope that the substance may relieve pain by its property of reducing the irritability of the myometrium. Results must be judged critically, in view of the great importance of psychic and other general factors in such conditions. It is, however, reliably reported that a few sufferers from primary dysmenorrhea have received striking benefit and that about 25 to 50 per cent have been definitely helped by progesterone. Treatment should begin three or four days before the expected onset of menstrual pain. One or 2 international units per day may be given at first, but if necessary the dose should be pushed up to 5 units or more before abandoning the experiment.

A thorough, well controlled study of this question is greatly to be desired.

After-Pains.—As shown by Lubin, Clarke and Reynolds,¹⁷ pain due to uterine contractions following

parturition is promptly relieved by 1 international unit of progesterone. No harmful effects have been reported, although theoretically at least there is a possibility of harm from relaxation of the uterus.

Metrorrhagia and Menorrhagia; Amenorrhea.—In the normal menstrual cycle the corpus luteum is present during the second half of the interval; the menstrual flow begins when the corpus luteum degenerates. Administered progesterone in normal monkeys postpones natural menstruation, and in castrate monkeys suppresses the artificial menstruation produced by estrogen deprivation.¹⁸ Progesterone has therefore been tried therapeutically in metrorrhagia and menorrhagia, and favorable results have been reported. In the special case of bleeding associated with glandular hyperplasia of the endometrium, another physiologic reaction may play a part. This disease is generally considered, on experimental grounds, to result from overaction of estrogenic hormones on the endometrium; progesterone may act beneficially either by cutting down the effectiveness of the estrogens, as it seems to do in the normal cycle,¹⁸ or by producing changes of the premenstrual type and thus in some way counteracting the tendency to bleeding. Until one knows exactly why the uterus bleeds in normal menstruation and in functional uterine disease, one can hardly offer a more precise explanation of therapeutic hopes or results.

For the present the treatment of functional bleeding must be left to specialists in gynecologic endocrinology for cautious experimentation after skilled clinical analysis of each case. Because of the danger that abnormal bleeding may be due to a benign or a malignant tumor, the general physician should not administer progesterone for uterine hemorrhage.

As to amenorrhea, endocrinologists know as yet little about the hormonal relations of such disturbances of the cycle. Here again the use of ovarian products is still quite experimental and must be worked out by clinical specialists.

Other Conditions.—Now that progesterone is becoming generally available, it is inevitable that it will be tried, both rationally and irrationally, for all sorts of diseases; such efforts are to be received with caution. Already there are reports of its use in the treatment of certain types of rhinorrhea, arthritis and disturbances of the thyroid. "Corpus luteum therapy" for hyperemesis gravidarum, once attempted with orally administered glandular preparations but long abandoned, is being revived with progesterone. Serious attempts are being made to relieve toxemias of pregnancy, especially eclampsia, with this substance, though apparently thus far without statistically better results than can be achieved by conservative general treatment.

EMPIRIC PREPARATIONS

A number of corpus luteum preparations are still on the market in tablet form for oral administration or in aqueous solution, which are not assayed for progesterone and contain at most very small amounts of this factor. The methods of preparation or of administration are often such as to remove or to destroy the progesterone; if these preparations contain any other useful substance, it is something unknown to science. Their use is quite empiric, and they will no doubt become obsolete now that genuine assayed progesterone-containing products are available.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

GENERAL AUTOMATIC ULTRA VIOLET SOLEIL LAMP, MODEL E-43 ACCEPTABLE

Manufacturer: General Automatic Corporation, Macedonia, Ohio.

The General Automatic Ultra Violet Soleil Lamp, Model E-43 provides ultraviolet radiation within the limits of the standards set by the Council for devices using the term "sunlamp." These standards require that the energy of wavelengths shorter than and including 2,800 angstroms shall not exceed 1 per cent of the total energy of wavelengths between 2,804 and 3,132 angstroms. Since these wavelengths fall in the spectral region of low erythematogenic action, the sunlamp is suitable for unsupervised use by the layman.

The S-4 burner used in the lamp is a Westinghouse unit. The firm submitted the following data:

Burner input watts	120
Total watts required	250
Line voltage	110-120
Primary amperes	2.2
UV output at 30", m. w. per cm ²	75
Rated burner life in hours.....	400

The lamp operates only on alternating current. Spectral ultraviolet radiation measurements were made on the S-4 lamp in a laboratory selected by the Council. These measurements showed that the radiation of wavelengths shorter than 2,800 angstroms is immeasurably small, and hence these lamps qualify as sunlamps as far as spectral quality (wavelength) of radiation is concerned.

In this investigation the lamp was placed close in front of the quartz-fluorite achromatic spectroradiometer, and the spectral intensities were measured with a vacuum thermopile. The relative spectral intensities (galvanometer deflections) corrected for absorption in the spectroradiometer are given in the accompanying table.

General Automatic
Ultra Violet Soleil
Lamp, Model E-43.

The radiation at 2,804 angstroms (and shorter if measurable) is about 0.75 per cent of the total wavelengths, including 3,132 angstroms and shorter. Mounted in an aluminum reflector the radiation at 2,894 angstroms and shorter, relative to the total, would be still lower; hence these lamps comply with the Council's requirements for acceptability of a sunlamp for spectral quality of ultraviolet radiation.

Relative Spectral Intensities

Wavelengths (Angstroms)	Relative Energy (Average of 3 Lamps) Microwatts per Square Cm.
3,132	7.96
3,024	2.59
2,967	1.15
2,894	0.28
2,804	0.09
Total	12.07

The S-4 burner is mounted in what is stated by the firm to be a "true parabolic reflector" 10½ inches in diameter and spun from 20 gage aluminum, with a highly polished reflecting surface. The operating switch is built in the lamp head above the reflector. A horizontal arm supports the reflector and is mounted on a vertical stand, which also is adjustable. The base is

14 inches in diameter, weighs 26½ pounds and is equipped with four ball bearing casters. The net weight of the unit is 35 pounds.

The Council on Physical Therapy voted to accept the General Automatic Ultra Violet Soleil Lamp, Model E-43 for inclusion on its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

OFFICE OF THE SECRETARY.

SULFAPYRIDINE (See New and Nonofficial Remedies, 1940, p. 494).

The following dosage forms have been accepted:

Tablets Sulfapyridine 0.5 Gm. (7½ grains).

Prepared by Eli Lilly & Co., Indianapolis.

No U. S. patent or trademark.

Pulverules Sulfapyridine 0.25 Gm. (3¾ grains).

Prepared by Eli Lilly & Co., Indianapolis.

No U. S. patent or trademark.

LIVER LIQUID PARENTERAL 4 U. S. P. INJECTABLE UNITS PER CC.-ARMOUR.—A sterile aqueous solution containing the nitrogenous nonprotein fraction G of Cohn preserved with 0.3 per cent of cresol. The daily intramuscular administration of 0.25 cc. of liver liquid parenteral-Armour has been demonstrated to produce a satisfactory hemopoietic response defined as 1 U. S. P. unit (injectable) when assayed in cases of pernicious anemia as required by the Council.

Actions and Uses.—Liver liquid parenteral-Armour is proposed for intramuscular injection in the treatment of pernicious anemia. See general article Liver and Stomach Preparations, New and Nonofficial Remedies, 1940, p. 320.

Dosage.—The daily administration of 0.5 cc. (2 U. S. P. injectable units) for six days is recommended. After this period the dose may be reduced to 0.25 cc. (1 U. S. P. injectable unit) daily until the blood picture is satisfactory. Thereafter, either the volume of the dose or the time interval between doses is adjusted according to the individual patient's needs.

Manufactured by the Armour Laboratories, Chicago. No U. S. patent or trademark.

Vials Liver Liquid Parenteral 4 U. S. P. Injectable Units per cc.-Armour, 1 cc.

Vials Liver Liquid Parenteral 4 U. S. P. Injectable Units per cc.-Armour, 5 cc.

Vials Liver Liquid Parenteral 4 U. S. P. Injectable Units per cc.-Armour, 10 cc.

To prepare liver liquid parenteral-Armour fresh U. S. government inspected mammalian livers (minced finely) are mixed with three volumes of water, then macerated and heated to 85° C. to remove coagulable protein. The resulting mixture is condensed in vacuo at low temperature to syrup consistency. Ethyl alcohol is added to a concentration of 70 per cent. The mixture is allowed to stand for eighteen hours or over night. The alcohol solution is withdrawn and placed under refrigeration for several days until no further precipitation occurs. The clear liquid is siphoned off, and the alcohol removed by negative pressure at low temperature. The resultant residue is dissolved in distilled water and adjusted so that 1 cc. represents 100 Gm. of fresh liver tissue. Cresol U. S. P., 0.3 per cent, is added and the liquid allowed to stand in the aseptic room until no further precipitation occurs. The clear supernatant liquid is passed through a Berkefeld filter and filled into 1, 5 and 10 cc. rubber-capped vials under aseptic conditions. The contents of the vials are tested for sterility and tissue irritants, such as toxic amines, before the product is released.

SODIUM IODIDE.—"When dried to constant weight at 120° C., contains not less than 99 per cent Nal. It contains not more than 5 per cent of water." U. S. P.

For standards see the U. S. Pharmacopeia under Sodii Iodidum.

Actions, Uses and Dosage.—See the general article Iodine Compounds for Systemic Use (New and Nonofficial Remedies, 1940, p. 290).

The following dosage forms have been accepted:

Ampules Sodium Iodide-Lakeside, 1.0 Gm. (15¼ grains), 10 cc.

Prepared by the Lakeside Laboratories, Inc., Milwaukee.

Ampules Sodium Iodide-Lakeside, 2.0 Gm. (31 grains), 10 cc.

Prepared by the Lakeside Laboratories, Inc., Milwaukee.

Ampules Sodium Iodide-Lakeside, 2.0 Gm. (31 grains), 20 cc.

Prepared by the Lakeside Laboratories, Inc., Milwaukee.

SATURDAY, FEBRUARY 15, 1941

THE PROPHYLAXIS OF RHEUMATIC FEVER

Although some evidence¹ tends to show that sulfanilamide is without therapeutic effect (and may even be dangerous) in the treatment of rheumatic fever, the reports of Thomas and France² in Baltimore and of Coburn and Moore³ in New York have indicated that the drug may be of prophylactic value in preventing the recurrence of rheumatic attacks. Its experimental use for this purpose was based on the series of observations made by Coburn during the past decade, which relate rheumatic activity to the presence of hemolytic streptococcus infections of the rhinopharynx.

Both groups of investigators thought that, if these infections of the throat could be prevented, rheumatic recrudescences might not occur. To accomplish this result, small doses of sulfanilamide were given daily to rheumatic subjects during the period of the year (October to June or July) in which the incidence of streptococcal infections of the pharynx is highest. The Baltimore investigators found that major rheumatic recrudescences did not occur in the groups which received sulfanilamide prophylaxis, while in New York, Coburn and Moore⁴ state that in their group of rheumatic subjects who were treated in a like manner "the incidence of rheumatic fever . . . was less than 1 per cent."

In this issue of THE JOURNAL Thomas, France and Reichsman⁵ report that, during the last four years, major rheumatic incidents were not observed in groups

of known rheumatic subjects who had been placed on daily prophylactic doses of sulfanilamide during the fall, winter and spring months. Another interesting point brought out in this paper is that the toxic effects resulting from this prolonged dosage with sulfanilamide were negligible.

While these reports present a hopeful picture for the use of sulfanilamide in the prophylaxis of rheumatic fever and certainly show that the drug may be used in small daily doses for long periods with comparative safety, the final evaluation of this method of prevention awaits results obtained in large, carefully controlled series of young rheumatic subjects. In view of the widespread occurrence and the crippling effects of rheumatic fever, it is to be hoped that interest in and support for such projects will be sufficient to permit a final evaluation of this promising lead in the prevention of rheumatic fever.

NONENDOCRINE THERAPY OF ENDOCRINE DISORDERS

The series of special articles comprising the second edition of *Glandular Physiology and Therapy*, now being published in THE JOURNAL under the auspices of the Council on Pharmacy and Chemistry, indicates progress in the treatment of glandular disorders and the increased availability of numerous potent endocrine preparations. These substances are being widely used for substitution, stimulation or suppression of glandular activity. The treatment of endocrine disorders is not, however, necessarily limited to the use of hormonal substances. When the mechanism of the hormonal action is understood, the therapeutic problem may sometimes be attacked successfully by the use of non-endocrine substances whose concentration in the body has been disturbed by the endocrine dysfunction. For example, in Addison's disease or insufficiency of the adrenal cortex, excretion of sodium is increased, and this is responsible for many of the symptoms and signs. Although the administration of cortical steroids restores the sodium concentration of the tissues, an increase in the intake of sodium salts (as sodium chloride) alone may correct significantly the disturbances due to adrenal insufficiency.

Similarly, a method has been recently devised for the treatment of premenstrual distress or tension without endocrine therapy. Greenhill and Freed¹ have postulated, on the basis that the ovarian hormones, among other steroids, have the property to cause salt and water retention in the body, that symptoms of distress which occur during the premenstrual period may be due to edema of the various organs of the body. Thus, certain types of "premenstrual" migraine,

irritability, nausea, abdominal distention and frank edema were explained by the increase in extracellular fluid of the central nervous system, intestine and subcutaneous tissue. These investigators have administered from 2 to 3 Gm. of ammonium chloride daily, or approximately one fourth to one half the average diuretic dose, to patients during the last half of the menstrual cycle in order to combat the increase in extracellular fluid following sodium retention. They report that this therapy eliminated to a large extent the development of the premenstrual distress or tension in a large proportion of their patients. Since premenstrual distress is of common occurrence, this therapeutic procedure would seem to be a useful contribution.

While much progress may be made through the use of endocrine preparations, therapy with these substances is not necessarily the ideal or only method of treating some endocrine disorders. Consideration of the fundamental properties of hormones may possibly lead to shortcuts in the correction of the appropriate dysfunction. Other methods, including surgery and radio-therapeutic measures, may be better indicated in some conditions than the administration of glandular principles.

PHYSICIANS OFFERED A "DEAL"

On January 13 postcards were mailed to various physicians in the Indiana area which read as follows:

Dear Doctor:—I would like to enter into an arrangement with you, requiring your full time service away from your office. Attractive opportunity and fine remuneration. Office space is provided. This is a permanent arrangement. The proposition is in Anderson, Indiana. If you are interested, wire collect, giving your phone number, so that I can call you.

B. Sherman
1148 W. Chicago Ave.
Chicago, Illinois

A check of the address indicated that its occupant is the Ritholz Optical Company. The Bureau of Investigation first dealt with the Ritholz optical concerns in an article in *THE JOURNAL*, July 25, 1925. Ten years later, in the July 6, 1935 issue, the Bureau reported, under the title "The Ritholz Frauds," a post office fraud order issued against the concern. Nine different trade styles were listed in this article, although not all of them were named specifically in the fraud order, some of them apparently being local concerns not employing the mails; namely, "Dr. Ritholz Optical Co., Inc.," "Dr. Ritholz Optical Co." and "Ritholz Optical Co." This article also called attention to the fact that the energetic action on the part of the Chicago Better Business Bureau had resulted in barring the facilities of Chicago newspapers and radio stations to these stores. Subsequently the Ritholz concern agreed to advertise in accordance with the standard practice of optometrists, and the Better Business Bureau announced this in its Bulletin. Later

THE JOURNAL carried reports of two law suits involving the National Optical Stores and Benjamin D. Ritholz. The first of these referred to the case of *Ritholz et al. v. North Carolina State Board of Examiners in Optometry et al.*, 18 F. Supp. 409, which was abstracted in *THE JOURNAL*, Dec. 11, 1937, page 2015; the second was that of *Esell et al. v. Ritholz et al.* (S. C.), 198 S. E. 419, which was abstracted in *THE JOURNAL*, July 1, 1939, page 88.

In 1934 the Federal Trade Commission issued an order against Benjamin D. Ritholz of Chicago, doing business under the names Chicago Dentists and Chicago Dental House, Inc., in connection with the promotion of a dental plate in interstate commerce. In 1937, subsequent to the appearance of the fraud order, the Federal Trade Commission issued a complaint against the National Optical Stores and Dr. Ritholz Optical Company for their activities in connection with the promotion of spectacles. Subsequently the Post Office Department issued a fraud order against the Chicago Dentists, Chicago Dental House and International Dental House for using the mails in the promotion of dental plates. In this fraud order Mr. Benjamin D. Ritholz is mentioned as "one of the proprietors of the above named concerns."

Finally, the name of the individual who signs the current postcard addressed to doctors is not new to the A. M. A. files. A card mailed from Louisville, Ky., on Sept. 28, 1936 read as follows:

Dear Doctor:—We have a proposition for a physician in Louisville. Attractive opportunity netting at least \$40.00 per week. Call, wire or telephone

B. Sherman
Brown Hotel
Louisville, Ky.

The Bureau of Investigation was informed by the State Department of Health of Kentucky at that time that this man represented the National Optical Stores Company of Chicago.

In March 1936 a note was mailed to some Ohio physicians from the address of the Ritholz Optical Company Building:

Dear Doctor:—We have an unusual proposition for an oculist which will require full time away from his office. The remuneration will be at least \$40.00 per week. The proposition is in Ohio. Wire or Telephone MONroe 2148 charges collect.

Sincerely yours,

L. Gerew
1148 W. Chicago Ave.
Chicago, Ill.

By engaging repeatedly in such practices, these concerns have shown their total disregard for the welfare of the American people and their desire to make a profit at the expense of the eyesight of the citizens of this country. Their effrontery in attempting to engage unsuspecting physicians to promote their activities is astounding. An ethical physician would not give the slightest consideration to alining himself with such an outfit.

Current Comment

AMERICAN MEDICAL ASSOCIATION ON TRIAL

In the Organization Section of this issue of THE JOURNAL begins the report of the trial on the indictment of the American Medical Association, the District of Columbia Medical Society, the Harris County Medical Society, the Washington Academy of Surgery and many individual physicians, which has been the subject of great medical interest since it was first filed in 1939. The report here published, while not verbatim, is sufficiently inclusive to supply readers with a full account of the proceedings. Indeed the statements to the jury by the attorneys for the prosecution and for the defense are given almost in toto because these two statements seem to indicate the nature of the procedure to be followed. Indications at the time when the trial began were for a duration of from four to six weeks. It is proposed week by week to present the transcript of as much of the evidence as can be made available, considering the difficulties of transcription and preparation of the material.

TRANSMISSION OF BACTERIA IN VENTILATING SYSTEMS

In present day air conditioning systems 90 per cent of the cooled air is often recirculated. The redistribution of air from an infected space to noninfected areas might conceivably become a factor in the spread of disease. In a recent study¹ of the role of ventilating systems in the transmission of micro-organisms, bacteria (*B. subtilis* spores), which can be readily distinguished from other organisms usually found in air, were introduced in two different ventilating systems and the distribution of the spores was studied. The first ventilating system, which was provided with a paper-tissue filter, was located in a small auditorium. In one instance the spores were introduced beyond the filter and were thus not filtered, and in another experiment the spores were introduced in front of the filter and the air carrying them was filtered before being circulated. Fifteen minutes after the spores were introduced beyond the filter, analyses indicated the presence of 21.9 organisms to 10 cubic feet of the air in the auditorium. One hour after the spraying of the spores no organisms could be found in the air. Fifteen minutes after spraying spores in front of the filters only 3.7 organisms were present in 10 cubic feet of the air and after an hour these too had disappeared. In another series of experiments spores were introduced at different points in the ventilating system of a large building. Analyses of the air in two rooms of the building showed a maximum concentration of organisms during the spraying, which in these experiments lasted for a twenty minute period or during a short period (one half hour) thereafter. The number of organisms then decreased rapidly and within a relatively short time the count

returned to a normal level. This rapid decrease is attributable to the dilution factor, and to the action of the filter, as well as to the loss occasioned by surfaces such as the walls and floor. These experiments were made under the most favorable conditions for the transmission of bacteria in ventilating systems, the number of spores being far in excess of that which might be possibly expected to occur normally and the spraying being done at advantageous points, and they demonstrate that bacteria may be spread in this way, although the menace seems slight. The problem merits further study from the point of view of public health.

THE RADIO AND HIGH FREQUENCY APPARATUS

Recently THE JOURNAL called attention to the discussions now going on between members of the medical profession, including representatives of the Council on Physical Therapy of the American Medical Association, and government officials relative to suitable manufacture or control of high frequency apparatus which interferes with radio reception. In Great Britain it has been found desirable in the prosecution of the war to place governmental restrictions on the use of such apparatus. It is now necessary in that country for any person with such apparatus in his possession to have a permit from the postmaster general for its operation. Apparatus included under the control is diathermy and electro-medical equipment which uses valves or spark coils. The unauthorized possession of such apparatus constitutes an offense under the defense regulations. The purpose of control is obviously to reduce the number of sources of electrical disturbance so that proper use of radio as a defense mechanism may continue.

VETERINARY MEDICINE ADVANCES

The increasingly scientific and technical character of veterinary medicine becomes apparent with the appearance of the first issue of the *American Journal of Veterinary Research*.¹ This medium was not established for the publication of surplus technical material. It is planned primarily to reflect some of the newer investigations in the field of veterinary medicine which now emanate not only from divisions of the government and of the state universities which are concerned with veterinary medicine but also from individual practitioners. The first number of this periodical—that for October 1940—contains articles on *Brucella abortus* vaccine, the use of soaps for destroying the streptococci of mastitis as well as research on various infections confined to animals. Some of the contents are concerned with the effect of diet on internal parasites and with ascorbic acid. There are other articles dealing with circulation, respiration and glandular changes in animals. Since much of this research may be of significance to human medicine, it is planned to index the contents of this periodical regularly in the *Quarterly Cumulative Index Medicus*.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY WAR DEPARTMENT

The following additional medical reserve corps officers had been ordered to extended active duty by the War Department, Washington, D. C., up to January 24:

ABLE, LeGrand Guerry, 1st Lieut., Spartanburg, S. C.
BAKER, Augustus Lynn, Major, Dover, N. J.
BEINAR, Peter Joseph, 1st Lieut., Chicago.
BRANNAN, Max, 1st Lieut., Coral Gables, Fla.
CALDEN, Willard S., 1st Lieut., Berkeley, Calif.
CASE, Robert Bowen, 1st Lieut., Oakland, Calif.
FRENCH, Adam James, 1st Lieut., Ann Arbor, Mich.
GOAD, Lloyd Henry, 1st Lieut., Oklahoma City.
GREEN, Sydney Harold, 1st Lieut., Alcatraz, Calif.
GREENSTEIN, Carl, 1st Lieut., Sheboygan, Wis.
GUYER, Herbert Bernard, 1st Lieut., Dorchester, Mass.
HAMLIN, Percy Gatling, Major, Williamsburg, Va.
HANNA, John Thomas, Major, Burlington, Iowa.
HARRISON, Charles Samuel, 1st Lieut., Clarksburg, W. Va.
HEIN, Walter Francis, Captain, Williams, Ariz.
HELMING, Oscar Clemens, 1st Lieut., La Jolla, Calif.
HERBERT, William Chapman, 1st Lieut., Spartanburg, S. C.
HOWARD, William Templeton, 1st Lieut., Covington, Tenn.
ICE, William Henry, Captain, Los Angeles.
JOHNSON, Maurice Eugene, Captain, Pleasant, W. Va.

JOHNSON, Neill, 1st Lieut., Stockton, Calif.
JONES, Harry Douglas, 1st Lieut., Nashville, Tenn.
KAUFMAN, Maurice, Captain, Cumberland, Ky.
KESCHNER, Harold Walton, 1st Lieut., New York.
LANGSDORF, Gordon C., 1st Lieut., San Leandro, Calif.
LEVIN, Grant, 1st Lieut., New York.
LEWISON, Edward Frederick, 1st Lieut., Baltimore.
LITTLE, William Wilbur, 1st Lieut., Washington Island, Wis.
LOKEN, Selmer Milo, 1st Lieut., St. Paul.
LYON, Edward, Jr., 1st Lieut., Williamsport, Pa.
MAGILL, Herbert Kelvin, 1st Lieut., Baltimore.
McCANDLESS, Garrett Clair, Captain, Franklin, Pa.
McCAULEY, Lewis Ross, 1st Lieut., Punxsutawney, Pa.
MOXNESS, Bennie Arthur, Lieut. Col., West Hartford, Conn.
PAULL, Ross, Major, La Jolla, Calif.
RAMO, Leon, Captain, Spivak, Colo.
RICKLES, George Abraham, 1st Lieut., Fort Steilacoom, Wash.
SHEA, Andrew W., 1st Lieut., Minneapolis.
SHEA, John D., 1st Lieut., Denver.
SIMS, John A., 1st Lieut., Colorado Springs, Colo.
SMITH, Frederick James Cunningham, 1st Lieut., Ardmore, Okla.
SNYDER, John Mendenhall, Captain, Rochester, Minn.
STERN, Siegfried, 1st Lieut., New Rochelle, N. Y.
WARREN, John Curtis, 1st Lieut., Bicknell, Ind.
WOODRUFF, Robert, 1st Lieut., Rochester, Minn.

FIRST CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty with the regular army by the Commanding General, First Corps Area, since January 24. The First Corps Area comprises the states of Maine, Vermont, New Hampshire, Rhode Island, Massachusetts and Connecticut.

BEEAKER, Vincent H., Lieut., Lewiston, Me., Fort Benning, Ga.
BROWN, Abe A., Major, Providence, R. I., Fort Benning, Ga.
CALCAGNI, Oscar H., Lieut., Morrisville, Vt., Fort Benning, Ga.
CANTER, Bernard, Lieut., Springfield, Mass., Fort Benning, Ga.
CARROLL, Francis B., Lieut., Great Barrington, Mass., Fort Benning, Ga.
COEN, William B., Lieut., Springfield, Mass., Army Medical Center, Washington, D. C.
CRANE, James E., Lieut., Stamford, Conn., Fort Benning, Ga.
CRISCUOLO, Joseph A., Lieut., New Haven, Conn., Fort Benning, Ga.
FENNO, Frederic R., Lieut., Brookline, Mass., Camp Edwards, Falmouth, Mass.
FULLER, Richard C., Lieut., Saxtons River, Vt., Fort Benning, Ga.

SECOND CORPS AREA

The following additional medical reserve corps officers had been ordered to active duty by the Commanding General, Second Corps Area, up to January 31. The Second Corps Area comprises the states of New York, New Jersey and Delaware.

BAGNER, Alan B., 1st Lieut., Jackson Heights, N. Y., Camp Livingston, La.
BEDELL, Harold, 1st Lieut., Long Island, N. Y., Fort Dix, N. J.
BELLANTONI, Adolph J., 1st Lieut., New York, Fort Hamilton, N. Y.
BERGAMINI, Herbert M., Major, New York, Carlisle Barracks, Pa.
BERGER, Morton, 1st Lieut., Howard Beach, N. Y., Fort Dix, N. J.
BERNSTEIN, Isidor, 1st Lieut., Brooklyn, Camp Livingston, La.
BOLKER, Abraham, 1st Lieut., Brooklyn, Camp Shelby, Miss.
BOTWIN, Nathan, 1st Lieut., New York, Fort McClellan, Ala.
BRIGNOLA, Gerald C., 1st Lieut., Hoboken, N. J., Fort Jay, N. Y.
CALABRESE, Edward St. J., 1st Lieut., Florida, N. Y., Camp Livingston, La.
CANTOR, Philip J., 1st Lieut., Brooklyn, Camp Shelby, Miss.
CHAIKINSKI, William A., 1st Lieut., Maspeth, N. Y., Camp Shelby, Miss.
COLONNA, Anthony R., 1st Lieut., Brooklyn, Fort McClellan, Ala.
DAUS, Milton J., Captain, Watkins Glenn, N. Y., Fort Ontario, N. Y.
DIASIO, Joseph S., Major, New York, Fort Hancock, N. J.
DICK, Morris M., 1st Lieut., New York, Fort Dix, N. J.
EISENBERG, David S., Captain, Port Byron, N. Y., Fort Benning, Ga.
ELSTEIN, Leo Herman, 1st Lieut., New York, Camp Shelby, Miss.
FALLER, Harry R., 1st Lieut., Port Jarvis, N. Y., Camp Livingston, La.
FOWLER, John D., Lieut. Col., Rochester, N. Y., Carlisle Barracks, Pa.

GOGGIO, Alfredo F., Lieut., Boston, Hq. F. A. C. Army Base, Boston.
GOLDMAN, Harry, Lieut., North Adams, Mass., Fort Benning, Ga.
HADLER, Arthur J., Lieut., Boston, Fort Benning, Ga.
KAVANAH, James S., Lieut., Methuen, Mass., Fort Devens, Mass.
LENTINO, Joseph W., Lieut., Clinton, Mass., Fort Benning, Ga.
LEVY, Phillip E., Lieut., Milford, Mass., Fort Benning, Ga.
LUCKNER, Wendelin G., Lieut., Stafford Springs, Conn., Fort Benning, Ga.
METCALF, John Thorpe, Captain, Lubeck, Maine, Fort Devens, Mass.
NEWTON, Aaron W., Lieut., Greenfield, Mass., Fort Benning, Ga.
PRIGOT, Aaron, Lieut., Roxbury, Mass., Fort Benning, Ga.
RATTENNI, Arthur, Lieut., Providence, R. I., Army Medical Center, Washington, D. C.
WHELAN, Edmund L., Lieut., East Boston, Mass., Fort Benning, Ga.
ZENTGRAF, Leo Paul, Lieut., Belmont, Mass., Fort Devens, Mass.

Orders Revoked

The order of the following medical reserve officer has been revoked:

WITTIG, Joseph E., Lieut., West Warwick, R. I.

FRANKEL, Israel A., 1st Lieut., Bronx, N. Y., Camp Livingston, La.
GARRETT, John L., 1st Lieut., Brooklyn, Camp Livingston, La.
GERSH, Irving, 1st Lieut., New York, Fort Dix, N. J.
GOLDBLOOM, Abraham A., Major, New York, Carlisle Barracks, Pa.
GRECO, Gabriel F., 1st Lieut., Richmond Hill, N. Y., Camp Livingston, La.
GREENBERG, Samuel, 1st Lieut., Brooklyn, Fort Dix, N. J.
HAUER, Emanuel, 1st Lieut., New York, Camp Livingston, La.
HINSON, Edward G., 1st Lieut., Oneida, N. Y., Fort Ontario, N. Y.
JACOBS, Matthew H., 1st Lieut., Brooklyn, Camp Livingston, La.
KAILANER, Jack R., 1st Lieut., Mount Vernon, N. Y., Camp Livingston, La.
KARPENSKI, Stephen J., Captain, Auburn, N. Y., Fort Benning, Ga.
KEMPNER, Ivan, 1st Lieut., Brooklyn, Camp Edwards, Mass.
KLEIN, Lawrence A., Captain, Rochester, N. Y., Fort Ontario, N. Y.
KLEIN, Sam I., 1st Lieut., Brooklyn, N. Y., Camp Livingston, La.
KOGEL, Marcus D., Major, Jamaica, L. I., N. Y., Carlisle Barracks, Pa.
KRAUS, Daniel M., 1st Lieut., New York, Camp Livingston, La.
LEFF, William A., 1st Lieut., Newark, N. J., Fort Benning, Ga.
LEIGH, Ted F., 1st Lieut., New York, Fort McClellan, Ala.
LILLEN, Milton, 1st Lieut., Newark, N. J., Fort Benning, Ga.
LIPKOFF, Clarence J., 1st Lieut., New York, Camp Livingston, La.
MASSUCCO, Frank J., 1st Lieut., Port Chester, N. Y., Fort Dix, N. J.
MAZAR, Steven A., Captain, Binghamton, N. Y., Fort Benning, Ga.
MILLER, Leo R., 1st Lieut., New York, Fort Devens, Mass.
NEUSTADTER, Arnold, 1st Lieut., Flushing, L. I., N. Y., Camp Livingston, La.
PACKARD, E. N., Lieut. Col., Saranac Lake, N. Y., Fort Dix, N. J.
PIAZZA, Thomas L., Captain, Albany, N. Y., West Point, N. Y.

PROTZMAN, Thomas B., Major, Englewood, N. J., Fort Monmouth, N. J.
 REIF, Irving L., 1st Lieut., Brooklyn, Fort Dix, N. J.
 SACHS, Elihu M., 1st Lieut., New York, Camp Livingston, La.
 SEIDEMANN, Irving, 1st Lieut., New York, Fort Dix, N. J.
 SETTEL, Edward, 1st Lieut., Brooklyn, Fort Dix, N. J.
 SHAPIRO, Sydney H., 1st Lieut., New York, Camp Livingston, La.
 SHLESINGER, Julius H., 1st Lieut., College Point, N. Y., Fort Dix, N. J.
 SOLOMON, Stanley E., Captain, New York, Fort Dix, N. J.
 SPERRAZZA, Augustine J., 1st Lieut., Astoria, L. I., N. Y., Fort Dix, N. J.

SPITZER, Lawrence L., 1st Lieut., New York, Camp Livingston, La.
 STEYAERT, Charles L., Captain, Lyons, N. Y., Fort Ontario, N. Y.
 STROBINO, Erastus E., Captain, Rochester, N. Y., Fort Ontario, N. Y.
 TAUBER, Max, 1st Lieut., Lynbrook, N. Y., Plattsburg Barracks, N. Y.
 TEPPER, Julius, 1st Lieut., Sunnyside, N. Y., Fort Dix, N. J.
 TONTAR, Silvio, 1st Lieut., Port Chester, N. Y., Fort Dix, N. J.
 TORNAMBE, Paul R., 1st Lieut., New York, Fort Dix, N. J.
 TURETSKY, Samuel, 1st Lieut., Brooklyn, Fort Dix, N. J.
 TYLAR, Norman E., Captain, Windsor, N. Y., West Point, N. Y.
 WEISS, Frank, 1st Lieut., Yonkers, N. Y., Fort Dix, N. J.
 WEISS, Murray Arthur, Major, New York, Fort Monmouth, N. J.
 WERTER, Nathan, 1st Lieut., Brooklyn, Fort Dix, N. J.

SEVENTH CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Seventh Corps Area. The Seventh Corps Area comprises the states of North Dakota, South Dakota, Minnesota, Nebraska, Iowa, Kansas, Missouri, Arkansas, and Wyoming.

BARGER, John Alexander, 1st Lieut., St. Louis, Camp Joseph T. Robinson, Ark.
 BRILLHART, Everett Guy, 1st Lieut., Shelby, Neb., Camp Joseph T. Robinson, Ark.
 BURLINGAME, David Albert, 1st Lieut., Minneapolis, William Beaumont Gen. Hosp., El Paso, Texas.
 DOSS, William Norman, 1st Lieut., Leon, Iowa, Camp Murray, Wash.
 HABERER, Justin Jerome, 1st Lieut., St. Louis, Fort Ord, Presidio of Monterey, Calif.
 HARMAN, Leo Dow, Major, Pawnee City, Nebr., Hot Springs, Ark.
 HAWKINSON, Raymond Paul, Captain, Robbinsdale, Minn., Fort Des Moines, Iowa.
 HENDERSON, Richard Gray, 1st Lieut., St. Louis, El Paso, Texas.
 HENDERSON, Robert Wesley, Captain, Bismarck, N. D., Camp Joseph T. Robinson, Ark.
 HOLMES, Charles King, Lieut. Col., Minneapolis, Hot Springs, Ark.
 JEWELL, Iverson Howard, Major, Paris, Ark., Hot Springs, Ark.
 KEIM, John Harry, 1st Lieut., Kennett, Mo., Fort Francis E. Warren, Wyo.
 MCCOMAS, Marmaduke D., Captain, Courtland, Kan., Fort Leavenworth, Kan.
 MULDOON, John Kennedy, Major, Omaha, Fort Ord, Calif.
 POTASHNICK, Robert, 1st Lieut., St. Louis, Camp Grant, Ill.
 RENICK, Fred Taylor, Captain, Lawrence, Kan., Fort Sam Houston, Texas.
 ROBERTS, John Richard, 1st Lieut., Brentwood, Mo., El Paso, Texas.
 ROSENFELD, Abraham Benjamin, Captain, Hibbing, Minn., Hot Springs, Ark.
 SARTORIUS, Herman Carl, Captain, Garden City, Kan., Fort Sam Houston, Texas.
 SATHER, Russell Olay, Captain, Crookston, Minn., El Paso, Texas.
 SELMAN, Ralph Jackson, Lieut. Col., Ottumwa, Iowa, El Paso, Texas.
 SHEINKOPF, Jacob Allan, Captain, Minneapolis, Hot Springs, Ark.

SMITH, Herman Joseph, 1st Lieut., Des Moines, Iowa, Fort Ord, Presidio of Monterey, Calif.
 SMITH, Louis Joseph, 1st Lieut., New Madrid, Mo., El Paso, Texas.
 SHELTON, Harold Jordan, Captain, St. Louis, Hot Springs, Ark.
 WEIR, Don Clair, 1st Lieut., Griswold, Iowa, El Paso, Texas.

Orders Revoked

ADLER, Morton William, 1st Lieut., Vandalia, Mo., Fort Snelling, Minn.
 ATKINSON, George Stanford, 1st Lieut., White Earth, Minn., Fort Snelling, Minn.
 BETTLER, Philip Leon, 1st Lieut., Sioux City, Iowa, Rolla, Mo.
 BORGMAYER, Henry John, 1st Lieut., Dodge, Neb., Fort Leonard Wood, Mo.
 BRANCH, James W., 1st Lieut., Hope, Ark., Camp Grant, Ill.
 BRYAN, Emery Clarence, 1st Lieut., Eric, Kan., Jefferson Barracks, Mo.
 CONLIN, Leo V. James, 1st Lieut., St. Paul, Carlisle Barracks, Pa.
 GRAY, Herschel Frederick, 1st Lieut., Little Rock, Ark., Fort Snelling, Minn.
 HAINES, Diedrich Jansen, 1st Lieut., Des Moines, Iowa, Camp Grant, Ill.
 HUDGEL, Lawrence Eugene, 1st Lieut., North Platte, Neb., Carlisle Barracks, Pa.
 JOHNSON, Marvin A., 1st Lieut., Plainview, Neb., Fort Snelling, Minn.
 LOTMAN, Harry Alfred, 1st Lieut., Lincoln, Neb., Carlisle Barracks, Pa.
 MACLEOD, Sherburne, 1st Lieut., Wichita, Kan., Fort Snelling, Minn.
 MARTIN, Melvin Cecil, Captain, Newton, Kan., Carlisle Barracks, Pa.
 MILLER, Richard White, 1st Lieut., Fayetteville, Ark., Jefferson Barracks, Mo.
 NEDERHISER, Morgan Ira, 1st Lieut., Cascade, Iowa, Carlisle Barracks, Pa.
 SHERMAN, Kenneth Eugene, 1st Lieut., Sturgis, S. D., Carlisle Barracks, Pa.
 SIMONTON, Kinsey MacLeod, 1st Lieut., Rochester, Minn., Camp Grant, Ill.
 SMITH, Frederick Abbott, 1st Lieut., Rochester, Minn., Camp Grant, Ill.
 STERNHILL, Isaac, Captain, Council Bluffs, Iowa, Camp Grant, Ill.
 STILL, Richard Mathias, 1st Lieut., Lincoln, Neb., Camp Grant, Ill.
 STRATHERN, Carleton S., 1st Lieut., St. Peter, Minn., Camp Grant, Ill.
 UIHLEIN, Alfred, 1st Lieut., Rochester, Minn., Camp Grant, Ill.
 VAUGHN, Louis Dysart, 1st Lieut., Rochester, Minn., Camp Grant, Ill.

EIGHTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Eighth Corps Area. The Eighth Corps Area comprises the states of Colorado, Arizona, New Mexico, Oklahoma and Texas.

ADAMS, Clinton E., Captain, Abilene, Texas, Fort Bliss, Texas.
 ALEXANDER, Arthur B., 1st Lieut., Spur, Texas, Fort Sill, Okla.
 APPEL, Myron Henry, 1st Lieut., Alice, Texas, Fort Sam Houston, Texas.
 BADT, Morris B., Lieut. Col., Fort Worth, Texas, Camp Hulen, Texas.
 BAILEY, William H., Lieut. Col., Oklahoma City, Fort Sill, Okla.
 BOYD, Granberry Davis, Jr., Captain, San Antonio, Texas, Fort Sam Houston, Texas.
 BOYKIN, James M., 1st Lieut., Taft Texas, Station Hospital, Fort Sam Houston, Texas.
 BOYSEN, Arthur E., Captain, McAllen, Texas, Fort Sam Houston, Texas.
 CLAUNCH, Dewitt, 1st Lieut., Comanche, Texas, Fort Sill, Okla.
 COHEN, Matthew, 1st Lieut., Phoenix, Ariz., Fort Sill, Okla.
 DAYWITT, Alvin L., Captain, Denver, Fort Sill, Okla.
 EWING, Ferdinand Stanley, Captain, Sinton, Texas, Fort Sam Houston, Texas.
 FRIEDLAND, Joseph D., 1st Lieut., Denver, Fort Sill, Okla.
 FRAWLEY, John Thomas, 1st Lieut., McAllen, Texas, Fort Sill, Okla.
 GERODETTI, Orlando F., Captain, San Antonio, Texas, 45th Division, Fort Sill, Okla.
 GOEN, Rayburne W., 1st Lieut., Denver, 45th Division, Fort Sill, Okla.
 GREEN, LaThaggar, Jr., 1st Lieut., Muleshoe, Texas, Fort Sill, Okla.
 HANNA, William Ray, 1st Lieut., Ladonia, Texas, Camp Hulen, Texas.
 HAYNES, Henry M., Jr., 1st Lieut., Gatesville, Texas, Fort Sill, Okla.
 HESTAND, Haskell E., 1st Lieut., Odessa, Texas, Fort Sill, Okla.
 HOLLS, Lynn E., 1st Lieut., Hollis, Okla., Fort Sam Houston, Texas.
 HOOKER, Lyle, 1st Lieut., Houston, Texas, Camp Hulen, Texas.
 JONES, William Ansel, Captain, Whiteriver, Ariz., Fort Sam Houston, Texas.
 JORNS, Cecil F., 1st Lieut., Houston, Texas, Fort Sam Houston, Texas.
 KENNEDY, Virgil N., Captain, Newkirk, Okla., Fort Sill, Okla.

KING, Everett G., 1st Lieut., Duncan, Okla., Fort Sill, Okla.
 KIRKPATRICK, Louis P., 1st Lieut., Houston, Texas, 45th Division, Fort Sill, Okla.
 MATTHEWS, Choice B., 1st Lieut., Kerrville, Texas, Fort Sam Houston, Texas.
 MCCARTY, David Wilson, Jr., 1st Lieut., Longmont, Colo., Fort Sam Houston, Texas.
 McMILLAN, George Sherill, 1st Lieut., Hurley, N. Mex., Fort Sill, Okla.
 MOORE, Masters H., 1st Lieut., Tyler, Texas, Fort Sill, Okla.
 NEWMAN, Meshach H., 1st Lieut., Shattuck, Okla., Fort Sill, Okla.
 OWERS, Albert, 1st Lieut., Temple, Texas, Fort Sam Houston, Texas.
 PAGE, Donald F., 1st Lieut., Boulder, Colo., Fort Bliss, Texas.
 PRYOR, Victor W., 1st Lieut., Holdenville, Okla., Fort Sill, Okla.
 RAFF, Joseph Samuel, Captain, Madill, Okla., Fort Sill, Okla.
 RHEA, Robert L., Jr., 1st Lieut., San Antonio, Texas, Fort Sam Houston, Texas.
 RICKS, James Ralph, Jr., 1st Lieut., Oklahoma City, Fort Sill, Okla.
 RIKE, Bernard J., 1st Lieut., Wagoner, Okla., 45th Division, Fort Sill, Okla.
 RIKLIN, Henry Hyman, 1st Lieut., Safford, Ariz., Fort Sam Houston, Texas.
 RITCH, Allen T., Major, San Antonio, Texas, Fort Sam Houston, Texas.
 ROBERTSON, Adolph H., 1st Lieut., Miles, Texas, 45th Division, Fort Sill, Okla.
 ROBINETT, James Bradley, Jr., 1st Lieut., Houston, Texas, Fort Sill, Okla.
 ROSS, Lloyd I., 1st Lieut., San Antonio, Texas, Fort Sam Houston, Texas.
 SCHILLER, Nelson Lorenz, Captain, Brenham, Texas, Fort Bliss, Texas.
 SHOTS, Chester C., 1st Lieut., Pleasanton, Texas, Fort Sam Houston, Texas.
 SHUPE, Reed Dalton, Captain, Phoenix, Ariz., Fort Bliss, Texas.
 SIEVERS, Walter Andrew, 1st Lieut., Gonzales, Texas, Camp Grant, Ill.
 SMITH, Leslie B., 1st Lieut., Phoenix, Ariz., Fort Sam Houston, Texas.
 WEINER, Harry Ida, 1st Lieut., Cave Creek, Ariz., Fort Bliss, Texas.
 WOODALL, John B., 1st Lieut., Kerrville, Texas, Camp Hulen, Texas.
 WOODARD, Thad L., 1st Lieut., Dallas, Texas, Fort Brown, Texas.
 WOODS, Haddon Benjamin, Captain, Refugio, Texas, Fort Sill, Okla.
 WOODSON, Orville McClure, 1st Lieut., Poteau, Okla., Fort Sill, Okla.
 WORD, Lee B., 1st Lieut., Bartlesville, Okla., Fort Sill, Okla.

Orders Revoked

Orders on the following officers, reported previously, have been revoked:

BADEN, Ervin Edgar, 1st Lieut., Raymondville, Texas.
BAMBERGER, Paul J., 1st Lieut., Climax, Colo.
BARNES, Johnson Peyton, 1st Lieut., Houston, Texas.
BICKLEY, Estill T., 1st Lieut., Corpus Christi, Texas.
BROWN, Robert N., 1st Lieut., Denver.
BUCHTEL, Henry A., 1st Lieut., Denver.
CARSON, John M., 1st Lieut., Shawnee, Okla.
CONTE, Raphael, 1st Lieut., Houston, Texas.
DAVIS, Charles O., Major, Houston, Texas.
DEVORE, Neal N., Captain, Houston, Texas.
EWERT, William A., 1st Lieut., Kingsville, Texas.
FRENCH, A. James, 1st Lieut., Ann Arbor, Mich.
GALLAHER, Frank C., 1st Lieut., Shawnee, Okla.
GLASIER, Wm. Albert, 1st Lieut., Carlsbad, N. M.
GOEN, Rayburne W., 1st Lieut., Denver.
JAFFA, Bertram B., Captain, Denver.

The following additional medical reserve corps officers had been ordered to extended active duty by the Commanding General, Ninth Corps Area, up to January 26. The Ninth Corps Area comprises the states of Washington, Montana, Oregon, Nevada, Utah, California and Idaho.

ALDEN, Warren H., 1st Lieut., John Day, Ore., Fort Lewis, Wash.
ALDRICH, Albert T., 1st Lieut., Los Angeles, Camp San Luis Obispo, Calif.
BARAFF, Albert A., Captain, Hollywood, Calif., Nacimiento, Calif.
BENNETT, Louis C., Captain, Los Angeles, Nacimiento, Calif.
BISWELL, Roger, 1st Lieut., Baker, Ore., Fort Lewis, Wash.
BURNS, Edgar M., 1st Lieut., Portland, Ore., Fort Lewis, Wash.
BURNS, John K., 1st Lieut., Spokane, Wash., 3d Division, Fort Lewis, Wash.
CAMPISI, Dominic A., 1st Lieut., San Jose, Calif., Camp San Luis Obispo, Calif.
CANIPAROLI, Sante D., Captain, Portland, Ore., 3d Division, Fort Lewis, Wash.
COMROE, Leon B., 1st Lieut., San Francisco, Camp San Luis Obispo, Calif.
COUGHLIN, William F., Captain, Carmel, Calif., Fort Ord, Calif.
DITTO, Hugh H., 1st Lieut., Los Angeles, Nacimiento, Calif.
DENNEN, Charles, 1st Lieut., Seattle, 29th Engineer Battalion, Portland, Ore.
DOROSHOW, George D., Captain, Huntington Park, Calif., Nacimiento, Calif.
ESPERSEN, Ruben W., Captain, Klamath Falls, Ore., Fort Lewis, Wash.
FISH, Lester W., Major, Los Angeles, Nacimiento, Calif.
GOLDENBERG, Julius L., 1st Lieut., Los Angeles, Camp San Luis Obispo, Calif.
GOURSON, Nathaniel E., 1st Lieut., Maywood, Calif., Camp San Luis Obispo, Calif.
GUNDERSON, Ernest O., 1st Lieut., Berkeley, Calif., Fort Lewis, Wash.
GUTHRIE, Myron S., 1st Lieut., Bakersfield, Calif., Camp San Luis Obispo, Calif.
HAFT, Stanley S., 1st Lieut., Los Angeles, Nacimiento, Calif.
HALLER, Austin P., 1st Lieut., Los Angeles, Nacimiento, Calif.
HANSEN, Alex F., 1st Lieut., Long Beach, Calif., Camp San Luis Obispo, Calif.

JONES, Edmund D., Captain, Beaumont, Texas.
JOHNSTON, Lawrence W., 1st Lieut., Terrell, Texas.
KIRKPATRICK, Louis P., 1st Lieut., Houston, Texas.
LoBELLO, Leon, 1st Lieut., Dallas, Texas.
McMILLAN, James M., 1st Lieut., Vinita, Okla.
MITCHELL, Holland C., Captain, San Antonio, Texas.
NICHOLSON, R., Jr., Major, San Antonio, Texas.
ROUTON, Benj. C., 1st Lieut., Oklahoma City.
STURM, Charles E., Captain, San Antonio, Texas.
WALKER, Glen H., 1st Lieut., Coolidge, Ariz.
WILLIS, Raymond S., Captain, Dallas, Texas.

CORRECTION

Lieutenant Jeter.—In THE JOURNAL, January 18, page 239, under Eighth Corps Area, in the list of medical reserve officers ordered to active duty, the name Peter, James R., 1st Lieut., Ennis, Texas, Fort Bliss, Texas, should have been Jeter, James R.

NINTH CORPS AREA

HARBAUGH, Oril S., Captain, San Diego, Calif., Fort Roscerans, Calif.
HAVENHILL, Asher D., 1st Lieut., Santa Cruz, Calif., Fort Ord, Calif.
HIGGINS, John W., 1st Lieut., Los Angeles, Camp San Luis Obispo, Calif.
HOLLANDER, Frederick G., 1st Lieut., San Diego, Calif., Fort Roscerans, Calif.
HOZUVICKA, Otto A., 1st Lieut., San Diego, Calif., Nacimiento, Calif.
HULL, Earl T., Jr., 1st Lieut., Los Angeles, Riverside, Calif.
JOHNSON, Richard P., 1st Lieut., Oakland, Calif., Fort Winfield Scott, Calif.
LAYDEN, Milton, 1st Lieut., Los Angeles, Camp Haan, Riverside, Calif.
LEWIS, Herbert D., 1st Lieut., Hood River, Ore., Fort Lewis, Wash.
McCREARY, James H., 1st Lieut., Los Angeles, Nacimiento, Calif.
MAKOWER, Melvin L., 1st Lieut., Berkeley, Calif., Presidio of San Francisco.
MATSON, James R., 1st Lieut., San Diego, Calif., Torrey Pines, Calif.
MICHENER, John M., 1st Lieut., Pomona, Calif., Camp Haan, Riverside, Calif.
MILLS, Victor D., 1st Lieut., The Dalles, Ore., Fort Lewis, Wash.
NICOLA, Quintus, 1st Lieut., Montebello, Calif., Nacimiento, Calif.
PECKHAM, George M., Captain, Oakland, Calif., Presidio of San Francisco.
RASKIND, Robert, 1st Lieut., Los Angeles, Camp Haan, Riverside, Calif.
RUBERSTEIN, Victor G., 1st Lieut., Los Angeles, Camp Haan, Riverside, Calif.
SCHMIDT, Philipp E., Captain, Glendale, Calif., Fort Ord, Calif.
SCHNEIDER, Leo, Captain, Portland, Ore., Fort Lewis, Wash.
SHELTON, Robert M., 1st Lieut., Inglewood, Calif., Nacimiento, Calif.
SKOLLER, Julius, 1st Lieut., Los Angeles, Riverside, Calif.
SMITH, William P., Major, Columbus, Mont., Camp Murray, Wash.
STEINBERG, Saul S., 1st Lieut., Oakland, Calif., Nacimiento, Calif.
TAIT, Arnold C., 1st Lieut., Rosalind, Wash., 3d Division, Fort Lewis, Wash.
TURLEY, Gerald W., 1st Lieut., Goldendale, Wash., Fort Lewis, Wash.
WEINBERG, Samuel J., 1st Lieut., Los Angeles, Nacimiento, Calif.

Relieved from Active Duty or Orders Revoked

DANIELE, Joseph A., 1st Lieut., assigned to Buckho Ranch, Calif., reported on January 18, orders revoked.
YUSKIS, Anton S., 1st Lieut., assigned to 7th Division, Fort Ord, Calif., reported on Dec. 26, 1940, relieved from active duty January 17.

HEALTH REPORT ON UNITED STATES TROOPS

The *Monthly Health Review* for troops in the United States, issued by the Surgeon General's Office, Washington, D. C., for the four weeks ended Oct. 26, 1940, shows that the general admission rate for these troops was 740 per thousand as compared to 566 for the previous month, communicable diseases having been largely responsible for the increase. The rate for the respiratory group of diseases rose to 212.2 from 114.1 for September. Venereal diseases showed a slight decline to 39.1 from 44 for the previous month, being still well above the rate for the same period in the previous year. Two cases of typhoid were reported during the month, one in the Seventh Corps Area and one in the Eighth Corps Area; there was one case of typhus fever in the Fourth Corps Area and one of Malta fever in the Ninth Corps Area. The rate for injuries showed an increase over that for September, 119 as compared to 87. The noneffective rate remained low, 21.7. The death rate was 2.61 per thousand. Of the seventy-nine deaths, four were due to adenocarcinoma, one to meningitis, three to tuberculosis, one to pneumonia, two to appendicitis, twenty-three to automobile accidents, twelve to airplane accidents, three to motorcycle accidents, six to suicide, three to homicide and two to drowning.

NEW HOSPITAL AT SCOTT FIELD

A hospital and infirmary and one barracks will be constructed at Scott Field, Ill., at an estimated cost of \$450,000, newspapers report. The hospital will have a capacity of two hundred and ninety-five beds and be of the cantonment type, intended to relieve crowding in the present facilities.

SHIPLOAD OF WAR RELIEF SUPPLIES FOR GREECE

Loaded with foodstuffs and other relief supplies purchased through the Congressional appropriation for relief of civilians in war torn nations, and the remainder purchased from Red Cross funds, the Greek steamer *Kassandra Louloudis* has just sailed for Greece with a cargo weighing nearly 9,000 tons, values in excess of \$1,000,000. In the cargo are \$150,000 worth of hospital and surgical supplies, 1,000,000 quinine tablets, 1,500,000 surgical dressings, 20,000 pounds of woolen yarn, 20,000 pairs of children's shoes, 80,000 suits of underwear, 100,000 blankets, 260,000 garments made by Red Cross volunteer workers, 10,000,000 pounds of foodstuffs and ten small trucks to be used for the distribution of these supplies in Greece under the direction of American Red Cross representatives.

ORGANIZATION SECTION

AMERICAN MEDICAL ASSOCIATION ON TRIAL

THE TRIAL OF THE CASE OF THE UNITED STATES OF AMERICA
VS.

THE AMERICAN MEDICAL ASSOCIATION, A CORPORATION, THE MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA, A CORPORATION, THE HARRIS COUNTY MEDICAL SOCIETY, AN ASSOCIATION, THE WASHINGTON ACADEMY OF SURGEONS, AN ASSOCIATION, ARTHUR CARLISLE CHRISTIE, COURSEN BAXTER CONKLIN, JAMES BAYARD GREGG CUSTIS, WILLIAM DICK CUTTER, MORRIS FISHBEIN, THOMAS ALLEN GROOVER (DECEASED), ROBERT ARTHUR HOOE, ROSCO GENUNG LELAND, THOMAS ERNEST MATTINGLY, LEON ALPHONSE MARTEL, FRANCIS XAVIER MCGOVERN, THOMAS EDWIN NEILL, EDWARD HIRAM REEDE, WILLIAM MERCER SPRIGG, WILLIAM JOSEPH STANTON, JOHN OGLE WARFIELD JR., OLIN WEST, PRENTISS WILSON, WILLIAM CREIGHTON WOODWARD, WALLACE MASON YATER, JOSEPH ROGERS YOUNG.

This case came on for trial before Associate Justice James M. Proctor and a jury in Criminal Division No. 2 of the District Court of the United States in the District of Columbia at 10 o'clock a. m., Wednesday, February 5.

On behalf of the United States appeared

John H. Lewin, Special Assistant to the Attorney General.
Grant W. Kelleher, Special Assistant to the Attorney General.

George B. Haddock, Special Attorney, Department of Justice.

Edward J. Hickey Jr., Special Attorney, Department of Justice.

Walton Allen, Special Attorney, Department of Justice.

Compton Timberlake, Special Attorney, Department of Justice.

On behalf of defendants Medical Society of the District of Columbia, Washington Academy of Surgeons, Arthur Carlisle Christie, Coursen Baxter Conklin, James Bayard Gregg Custis, William Dick Cutter, Robert Arthur Hooe, Thomas Ernest Mattingly, Leon Alphonse Martel, Francis Xavier McGovern, Thomas Edwin Neill, Edward Hiram Reede, William Mercer Sprigg, William Joseph Stanton, John Ogle Warfield Jr., Wallace Mason Yater and Joseph Rogers Young:

Charles S. Baker.

William E. Leahy.

Warren Magee.

On behalf of defendants American Medical Association, Harris County Medical Society, Morris Fishbein, Rosco Genung Leland, Olin West and William Creighton Woodward:

Edwin M. Burke,

Seth W. Richardson,

Adrien Busick.

On behalf of defendant Prentiss Willson:

John B. Laskey.

The Proceedings

THE COURT:—Gentlemen, I assume you are ready to proceed.

Mr. Burke:—Except, your Honor, before you begin selecting a jury, we would like to present the document that I spoke to you about day before yesterday, for your consideration.

Mr. Magee:—They are the proposed motions, your Honor, with reference to parts of the record.

THE COURT:—I think we could take them up better after the jury is selected. I am anxious, gentlemen, to select a jury so that we may release jurors who are not needed. We have three panels here today. The other courts may need them.

THE COURT:—I want to address a moment the ladies and gentlemen who appear as prospective jurors. There are some seventy-eight of you, three panels; and I wish you all to carefully follow the information which will be given you by way of identification of this case and the parties connected therewith, so that it will not have to be repeated. In the first place, I wish to briefly identify the case as to the parties and as to the names of the defendants; so I will have to ask each individual, as your name is called, to stand and turn toward your right so that the ladies and gentlemen of the jury may see you for a moment. This is a prosecution entitled United States against the American Medical Association, a Corporation Incorporated

under the Laws of Illinois and having its office and principal place of business in Chicago; the Medical Society of the District of Columbia, a corporation having its office and principal place of business in the District of Columbia; Harris County Medical Society, an unincorporated association having its office and principal place of business in Houston, Harris County, Texas; Washington Academy of Surgeons, an unincorporated association having its office and principal place of business in the District of Columbia. And then the following named individual defendants, all of whom I understand to be physicians, either of this city or of some other city.

The court called the name of each defendant, who stood as called except as otherwise noted.

THE COURT:—Where is Dr. Conklin? Has he been here?

Mr. Baker:—I heard from him day before yesterday. It seemed then that he had a desperately ill infant on his hands, and that is probably the difficulty.

THE COURT:—He will probably be here. Do you expect him here?

Mr. Baker:—Oh, absolutely.

THE COURT:—Will you call my attention to him as soon as he arrives?

Mr. Baker:—Yes, sir.

THE COURT:—The indictment against these defendants is for violation of the so-called Sherman Anti-Trust law. Charges against the associations and the individual defendants, in substance, are that, beginning in January, 1937, or shortly thereafter, and continuing to the date of the indictment, which was Dec. 20, 1938, the defendants and Washington hospitals and other persons to the grand jurors unknown combined and conspired together for the purpose of restraining trade in the District of Columbia in the following way: for the purpose of restraining Group Health Association, Inc., in its business of arranging for the provision of medical care and hospitalization to its members and their dependents on a risk-sharing prepayment basis;

For the purpose of restraining the members of Group Health Association, Inc., in obtaining, by cooperative efforts, adequate medical care for themselves and their dependents from doctors engaged in group medical practice on a risk-sharing prepayment basis;

For the purpose of restraining the doctors serving on the medical staff of said Group Health Association, Inc., in the pursuit of their callings;

For the purpose of restraining doctors (not on the medical staff of Group Health Association, Inc.) practicing in the District of Columbia, including the doctors so practicing who are made defendants herein, in the pursuit of their callings;

For the purpose of restraining the Washington hospitals in the business of operating such hospitals.

Counsel representing the United States, will you arise and state your names for the benefit of the jury?

The various lawyers arose and stated their names.

THE COURT:—Now, ladies and gentlemen of the first panel, that is, of this criminal court, I wish you would follow these questions very carefully, and if your answers cannot properly

be manifested by silence, I wish you would indicate by raising your hands and rising so that you may answer. Before doing so, I wish to have you sworn.

The members of the panels were duly sworn by the Assistant Clerk. The Court then directed questions to the panel.

Do you know any of the defendants whose names have been called?

(Two prospective jurors stood.)

THE COURT:—Will you give your name, please?

Mr. Simmons:—My name is Lloyd J. Simmons.

THE COURT:—Who is it that you know?

Mr. Simmons:—I don't know him personally, but it is Dr. Martel.

THE COURT:—You say you do not know him personally.

What is the nature of your acquaintanceship?

Mr. Simmons:—He recently saved the life of my nephew's wife.

THE COURT:—Would that fact in any wise influence you in the consideration and determination of the case if chosen as a juror?

Mr. Simmons:—I think it would.

THE COURT:—You think you would have difficulty in determining the case fairly and impartially, solely upon the basis of the evidence?

Mr. Simmons:—Yes, sir.

Mr. Porter stated that he was acquainted with Dr. Yater in high school days.

THE COURT:—Do you still have contact with him in a social way?

Mr. Porter:—No, sir.

THE COURT:—Would that fact in any wise influence you in the consideration and determination of the case if you are drawn as a juror?

Mr. Porter:—No, sir; I don't think so.

THE COURT:—Is any juror acquainted with counsel or any member of the staff representing the Government on the one hand or the defendants on the other?

Mr. Reuben Acton stated that he used to know Mr. Magee, in childhood days, 15 or 20 years ago, but has not had any social or business contacts with him in recent years, and that fact would not in any wise influence him in consideration or determination of the case, if drawn as a juror.

Mr. Edward R. Hammer said that he knew Mr. Leahy socially, but that would not in any wise influence him in consideration or determination of the case, if drawn as a juror.

THE COURT:—Have you formed or expressed any opinion as to the guilt or innocence of the defendants?

Mr. Kenneth S. Barry said he had formed an opinion and that he could not lay it aside and base a verdict impartially upon the evidence.

Mr. Philip P. Keller also definitely formed one and would be embarrassed if drawn as a juror, or would have difficulty in laying aside that opinion.

THE COURT:—Are you related to any person who is a defendant in this case? Do you know of any relationship between you and any of the individual defendants whose names have been mentioned?

Are you related to anyone engaged in the practice of medicine, including doctors, nurses, and hospital officials?

Mr. Hammer stated he had a niece who made her home with his family, employed in Georgetown Hospital.

Mr. Herman Dodeck had a cousin, a doctor, whom he saw three or four times a year, and that it might influence him in consideration and determination of the case, if drawn as a juror.

Mr. Simmons also had a niece who is a nurse and thought it might influence him.

Mr. Joseph E. Taylor Sr., has a cousin who is a doctor and thought it might influence consideration and determination of the case. He sees him once a year, about Christmas time.

THE COURT:—Have any of the defendant doctors ever treated you or any one in your immediate family, that is, these doctors whose names have been called?

Mr. Simmons:—Dr. Christie treated our family.

Mr. McNeil:—Dr. Neill performed an operation on my wife.

THE COURT:—How long ago was that?

Mr. McNeil:—Ten years, I guess.

THE COURT:—Would that fact in any wise influence you in your consideration and determination of the case, if drawn as a juror?

Mr. McNeil:—No, sir.

THE COURT:—Are you, or is any member of your immediate family an employee of any doctor, nurse, or hospital?

THE COURT:—Are you related to any of the counsel in the case, that is, any of the attorneys whose names have been mentioned? (No response.)

Have any relations which you have had with persons engaged in the practice of medicine prejudiced you so that you could not impartially try the merits of this case? In other words, have you had any incident arise in your relations with any doctor which might operate to create a prejudice or bias in your mind? (No response.)

Have you any conscientious scruples against convicting doctors of violation of the anti-trust law? (No response.)

Are you acquainted with Mr. Thurman Arnold, who, as you know, is Assistant Attorney General in charge of trust prosecutions? (No response.)

Is any juror a member of Group Health Association or has he or she ever been a member of Group Health Association?

Miss Patterson:—My name is Miss M. Edith Patterson. I am a member of Group Hospitalization.

Mr. Timberlake:—That is a different organization, your Honor.

Mr. Barry:—I am also a member of Group Hospitalization.

Mr. Bieber:—I am a member of Group Hospitalization.

Mr. Irwin:—I am a member of Group Hospitalization.

Mr. Hammer:—I have group hospitalization. I don't know what group it is.

Mr. Simmons:—I belong to an organization.

THE COURT:—What is your organization?

Mr. Simmons:—Group Hospitalization.

Mr. Dodeck:—I have a policy in an association.

THE COURT:—Is it a regular life insurance policy?

Mr. Dodeck:—It is health and life insurance.

Mr. Mogruder:—I belong to Group Hospitalization.

THE COURT:—Is there any member of any family, an immediate relative, such as father, mother, brother, sister, son or daughter, who is or has been a member of Group Health Association? Confine yourselves at present to that particular name—Group Health Association. (No response.)

Is there any member of the panel who is or has been employed since Jan. 1, 1937, in any of the executive branches of the Government of the United States?

Mr. Simmons:—Reconstruction Finance Corporation.

Mr. Horad:—My name is Washington Horad. I am employed by the Post Office Department.

Miss Patterson:—National Guard Bureau, War Department.

Mr. Gage:—My name is Lawrence A. Gage. Veterans Administration.

Mr. Porter:—War Department.

THE COURT:—Has any member of the panel a near relative, such as husband, wife, father, mother, son or daughter, who is or has been since Jan. 1, 1937, employed in any branch of the Government?

Mr. Barry:—Yes, sir. My father is in the War Department.

Mr. Horad:—I have a brother employed in the Commerce Department, in the Census Bureau.

Mr. Dodeck:—I have a sister in the Federal Power Commission.

Mr. O'Neil:—My husband is in the Navy.

Mr. Marggraf:—My name is Charles A. Marggraf. My sister is in the Treasury Department, and I have a brother and sister in the Public Schools of the District of Columbia.

THE COURT:—This relates to branches of the Federal Government. That would be local. Your sister is in which department?

Mr. Marggraf:—The Treasury.

Mr. Focchino:—I have a sister-in-law in the Reconstruction Finance Corporation.

Mr. Hammer:—I have a sister in the Veterans Bureau.

Mr. Barry:—My wife worked in the Civil Service Commission and the Treasury Department.

Mr. Taylor:—I have a mother in the Treasury Department. My step-father is in the Guard Service.

THE COURT:—Where is your step-father?

Mr. Taylor:—The Guard Service at Arlington.

Mr. Walsh:—My sister is in the Federal Bureau of Investigation.

Mr. McDowell:—I have a sister-in-law in the Agriculture Department.

Mr. Simmons:—I have a brother in the Federal Housing.

THE COURT:—What do you say, gentlemen, if we excuse Mr. Simmons?

We will excuse you from answering any further questions. You need not leave for the moment. I will excuse several others in a few moments.

Mr. Mogruder:—My wife is in the Library of Congress.

Mr. Ayers:—I have a brother in the War Department.

Mr. Bieber:—My mother is in the Bureau of Engraving & Printing, and my wife is in the Farm Credit Administration. I also have an uncle in the Navy Yard—the United States Navy Yard, Washington.

Mr. Corens:—My daughter is in the Veterans Bureau. I have a daughter-in-law working in the Navy Yard.

A Prospective Juror:—Do you want to know about sisters-in-law and brothers-in-law?

THE COURT:—I do not think it goes quite that far. The question mentions husband, wife, father, mother, son, or daughter. The next question is: Are you a member of any of the so-called union groups among the Federal employees, such as the American Federation of Government Employees, the United Federal Workers of America, the Federal Personnel Association, the Customs Association, the United Government Workers, Incorporated, and the National Federation of Government Employees? Are you a member of any of those organizations?

Miss Patterson:—Yes.

THE COURT:—Of which one, please?

Miss Patterson:—The American Federation.

THE COURT:—Does any of you have any immediate relatives, such as husband, wife, father, mother, son, or daughter who is or has been since Jan. 1, 1937, a member of any such group?

THE COURT:—Have you or has any member of your immediate family ever been sued by a physician, or have you sued a physician? In other words, have you ever had any litigation with a physician, one way or the other?

(There was no response.)

THE COURT:—Does any one of you attend or subscribe to the teachings of the Christian Science Church?

(There was no response.)

THE COURT:—Does any one of you or does any one of your immediate relatives, as far as you know, subscribe to the principles of or attend as a member any medical group other than that to which the defendants belong, such as the osteopathic school, the chiropractic school, or the naturopathic school, or any of the so-called schools which offer a plan or a system of medical treatment differing from that of the physicians?

(There was no response.)

THE COURT:—Has any member of the panel ever had any occurrence to him which has aroused in him any antagonistic feelings toward a doctor, a physician, or any group of doctors or physicians? In other words, have you ever had any experience of an unpleasant nature that has left any ill feelings or antagonistic feelings toward a doctor or medical group of any kind?

(There was no response.)

THE COURT:—Have you any other knowledge of this case than that which you have learned in Court, as has just been outlined to you, such as from reading of it in the newspapers.

Mr. Keller:—Just from reading about it in the papers the last few days.

THE COURT:—You have already told us that you have a very fixed opinion?

Mr. Keller:—That is right.

THE COURT:—Then, I shall not pursue this matter any further with you.

Mr. Hammer:—I have so many doctors, nurses, and dentists visiting in my home, and we have talked this case over quite a bit, so I have formed an opinion on it.

THE COURT:—You have already answered it.

Mr. McNeil:—I read about it in the papers only Friday.

THE COURT:—You have not had any previous knowledge of it? You have just read of it in the newspapers?

Mr. McNeil:—Yes.

Mr. Barry:—I have read considerable about it and have discussed it with my friends.

THE COURT:—Is any one of you a patient of any doctor employed by Group Health Association, Incorporated?

Mr. Kelleher, of counsel for the Government, will read the names of those doctors who are associated with Group Health Association, for your information.

Mr. Kelleher:—Dr. Raymond E. Selders; Dr. Richard H. Price; Dr. Mario V. Scandiffo; Dr. Russell F. Cahoon; Dr. Clark P. Halstead; Dr. Charles J. Albright; Dr. Dorn S. Hower; Dr. Robert Crichton; Dr. Gerald Long; Dr. Virginus Dabney; Dr. R. A. Boe; Dr. Allan Lee; Dr. R. Stephen Hulburt; Dr. Charles P. Campbell; Dr. David Dantzig; Dr. Arthur Rosenbaum; Dr. Henry S. Murphy; Dr. K. Charles Latven; Dr. M. H. Levine; Dr. Henry Rolf Brown; Dr. Chase; Dr. Lewis Marshall; Dr. Hutton; Dr. Moretti; Dr. Bradley.

For the last few we do not have their first names or initials.

THE COURT:—You have heard the reading of that list. Are you or have you been a patient of any of the doctors whose names have been called?

(There was no response.)

THE COURT:—Do you know of any close relatives or friends who have been patients of any of those doctors?

Mr. Shelton:—I think he read the name Scandiffo there.

Mr. Kelleher:—That is correct.

Mr. Shelton:—About five years ago he attended my child one time.

THE COURT:—Does that fact in any wise influence you in your consideration or determination of the case as here outlined?

Mr. Shelton:—Not at all.

THE COURT:—How do you spell that doctor's name?

Mr. Lewin:—S-c-a-n-d-i-f-f-i-o.

Mr. Gage:—I have a close friend who was treated by Dr. Murphy in the Group Health.

THE COURT:—Dr. Murphy? Did you call his name?

Mr. Kelleher:—Yes, your Honor; Henry S. Murphy.

THE COURT:—Would that fact in any wise influence you in your consideration or determination of the case, Mr. Gage?

Mr. Gage:—No, your Honor, it would not.

THE COURT:—Have you or has any member of your family been a member of any association or corporation which furnished or arranged for the furnishing of medical service?

Mr. Barry:—I have mentioned mine before.

THE COURT:—Has any juror formed any opinion, or does any one of you now entertain any opinion, with respect to the merits of any group, association, or corporation formed for the purpose of rendering or arranging for the provision of medical service to persons on a prepayment basis?

Mr. Barry:—I mentioned that before.

THE COURT:—Are you or is any member of your family or is any close relative employed by, or have you or they ever been employed by, an organization known as the Twentieth Century Fund?

(There was no response.)

THE COURT:—Or the Good Will Fund—another organization known as the Good Will Fund?

(There was no response.)

THE COURT:—Or by the Edward A. Filene Good Will Fund?

(There was no response.)

THE COURT:—Or by an organization known as the Health Economics Association?

(There was no response.)

THE COURT:—Or by any Federal credit union?

(There was no response.)

THE COURT:—Have you formed any opinion as to the right of any hospital to select physicians for appointment to the regular staff or to the courtesy staff?

(There was no response.)

THE COURT:—Have you formed any opinion as to the right of Washington hospitals to prescribe rules and regulations concerning the care and treatment of patients admitted to hospitals?

(There was no response.)

THE COURT:—Have you formed any opinion as to the right of doctors to form associations and to adopt rules and regulations governing their professional relations with their patients and among themselves?

(There was no response.)

WITNESSES TO BE CALLED BY THE GOVERNMENT

THE COURT:—Now, members of the panel, among the witnesses whom the Government expects to call are the following. I wish you would follow their names, so that you may state whether or not you are acquainted with any of them:

Mrs. Elsie P. Sadler	Dr. R. Stephen Hulburt
Mrs. Mildred H. Cargill	Dr. Allan Lee
Caroline Christopher	Dr. Lee Thompson
Dorothy Cridland	Dr. Francis X. Richardson
Dorothy Ernsting	Dr. Mario Scandiffo
Catherine Hartenbourg	Dr. George B. Trible
Mrs. C. E. Johnson	James R. Adams
William C. Kirkpatrick	Miss Peggy O'Connor
Dr. Hugh Cabot	Mary Frances Stuart Maury
Dr. Michael Davis	Colonel Joseph Randall
Dr. Bowman C. Crowell	Anita Richardson
Raymond R. Zimmerman	Mrs. Caroline Reece Epperley
Miss Roseannette Barrent	Dr. V. J. Dardinski
William F. Penniman	William White Anderson, Jr.
Margaret Wilson	Mrs. Harriet A. Austin
Dr. Holman Taylor	Mrs. Edwina Austin Avery
Dr. J. C. Alexander	Mr. Hastings B. Avery
Dr. Walter A. Coole	Charles C. Hardin, Jr.
Dr. A. T. Talley	Mrs. Charles G. Hardin
Mrs. Ira C. Everett	Sherwood K. Booth
Dr. Alan Newmann	Miss Sara Abbott

After conference of attorneys with the Court concerning the jury the counsel returned to their seats.

The Assistant Clerk:—Jurors, as your names are called, please answer and take seats in the jury box.

(The prospective jurors took seats in the jury box, as follows):

Reuben Acton Jr.	Lawrence A. Gage
Edwin H. Ayers	Washington W. Horad
Edgar W. Bieber	Egbert H. Irwin
Albert E. Burley	Otho T. M. King
Hubert P. Corens	Eugene B. Magruder
Columbus Facchina	Charles A. Marggraf

THE COURT:—Now, gentlemen, the Government has the first challenge. If you have any challenge for cause, you will make the challenge on that basis, if it is for some individual juror; if not, make a peremptory challenge.

Mr. Lewin:—The Government has no challenges for cause.

THE COURT:—Do you care to exercise a peremptory challenge, or are you content with the jury?

Mr. Lewin:—We should like to exercise one peremptory challenge.

THE COURT:—Very well. Name the juror, please.

Mr. Lewin:—Mr. Albert E. Burley.

THE COURT:—Mr. Burley, you will step down, please.

(*Mr. Burley was excused.*)

The Assistant Clerk:—Mrs. Madelyn M. McDowell.

Mrs. McDowell:—Here.

The Assistant Clerk:—Please take seat No. 4.

(*Mrs. McDowell took seat No. 4.*)

THE COURT:—Now the defense may exercise a challenge, either for cause or peremptorily. If it is for cause, state that fact.

Mr. Leahy:—May I ask the indulgence of the Court for a moment? Might Mr. Lewin and I approach the bench?

THE COURT:—Yes.

(*Counsel for both sides approached the bench and conferred with the Court.*)

(*After a long conference on the question of lawyers and government employees on juries, the trial continued.*)

Mr. Leahy:—The defense will now exercise one of its peremptory challenges. We will excuse Mr. Corens.

The Clerk:—Ernest S. McNeil, please take the seat No. 5. (*Thereupon Ernest S. McNeil took seat No. 5 in the jury box.*)

THE COURT:—Now the Government challenge.

Mr. Lewin:—The Government exercised a peremptory challenge and asks that Mr. McNeil be excused.

THE COURT:—Mr. McNeil, you are excused.

The Clerk:—Mrs. Edna Hayes O'Neil, please take seat No. 5. (*Thereupon Mrs. Edna Hayes O'Neil took seat No. 5 in the jury box.*)

THE COURT:—Now, it is a defense challenge.

Mr. Leahy:—The defense will now exercise its peremptory challenge and excuse Edgar W. Bieber.

(*Thereupon Edgar W. Bieber, being excused, vacated the jury box.*)

The Clerk:—Miss M. Edith Patterson, please take seat No. 3. (*Thereupon Miss M. Edith Patterson took seat No. 3 in the jury box.*)

THE COURT:—It is the Government's turn.

Mr. Lewin:—The Government passes this time.

THE COURT:—That means you are content?

Mr. Lewin:—We are content, yes, your Honor.

Mr. Leahy:—May we approach the bench for just a moment, your Honor?

THE COURT:—You may.

(*Counsel for both sides approached the bench and conferred with the Court.*)

Mr. Leahy:—Now would your Honor ask Miss Patterson whether she had ever been employed in the office of any physician?

THE COURT:—Miss Patterson, will you stand, please?

Have you ever worked for any medical association or any physician, or anything of the sort?

Miss Patterson:—No.

(*At the conclusion of the foregoing conference, counsel returned to the trial table, and the trial proceeded as follows:*)

Mr. Leahy:—If the Court please, the defense will now excuse Miss Patterson.

(*Thereupon Miss M. Edith Patterson, being excused, vacated the jury box.*)

The Clerk:—Jesse Ellis Porter, please take seat No. 3.

(*Thereupon Jesse Ellis Porter took seat No. 3 in the jury box.*)

Mr. Lewin:—May I approach the bench your Honor?

(*Counsel for both sides approached the bench and conferred with the Court.*)

THE COURT:—Mr. Porter, will you stand, please? You stated that you knew Dr. Yater. I believe you told us what the nature of that acquaintanceship was, did you not?

Mr. Porter:—During our high school days we were together.

THE COURT:—And you have not had any social or business contact with him since, as I recall?

Mr. Porter:—No.

THE COURT:—That has been how long ago?

Mr. Porter:—Twenty years.

THE COURT:—I believe you stated that would, in no event, enter into your consideration, if you were chosen as a juror?

Mr. Porter:—That is correct, your Honor.

(*At the conclusion of the foregoing conference, counsel returned to the trial table and the trial proceeded as follows:*)

Mr. Lewin:—The Government is content with this jury.

Mr. Leahy:—Might we approach the bench for just a moment, if your honor pleases?

(*Counsel for both sides approached the bench and conferred with the Court.*)

THE COURT:—Mr. Gage will be excused and report to Judge Morris's court.

(*Thereupon counsel returned to the trial table and the trial proceeded as follows:*)

The Clerk:—Henry E. Preston, please take seat No. 7.

(*Thereupon Henry E. Preston took seat No. 7 in the jury box.*)

THE COURT:—Now it is the Government's challenge.

Mr. Lewin:—The Government asks that Mr. Preston be excused on a peremptory challenge.

THE COURT:—Very well. Mr. Preston will be excused.

(*Thereupon Henry E. Preston, being excused, vacated the jury box.*)

The Clerk:—Watson V. Shelton, please take seat No. 7.

(*Thereupon Watson V. Shelton took seat No. 7 in the jury box.*)

THE COURT:—It is the defendant's turn.

Mr. Leahy:—May we approach the bench?

(*Counsel for both sides approached the bench and conferred with the Court.*)

THE COURT:—Mr. Shelton will be excused; report to Judge Morris's court.

(*Thereupon Watson V. Shelton, being excused, vacated the jury box.*)

The Clerk:—Joseph F. Taylor Sr. please take seat No. 7.

(*Thereupon Joseph F. Taylor Sr. took seat No. 7 in the jury box.*)

THE COURT:—The Government might express its views now.

Mr. Lewin:—The Government is satisfied with this jury.

Mr. Leahy:—If the Court please, the defense accepts the jury.

THE COURT:—Very well: Swear the jury.

(*The jury, constituted as follows: Reuben Acton Jr., 33, salesman; Edwin H. Ayers, 46, gas dealer; Jesse Ellis Porter, 45, assistant engineer; Mrs. Madelyn M. McDowell, 44; Mrs. Edna Hayes O'Neil, 51, housewife; Columbus Facchina, 28, secretary-treasurer of the Charles Facchina Tile Company; Joseph F. Taylor Sr., 38, floor manager; Washington W. Horad, 45, mail carrier; Egbert H. Irwin, 39, salesman; Otho T. M. King, 31, salesman; Eugene B. Magruder, 41, foreman; Charles A. Marggraf, 32, salesman, was duly sworn to try the issues in the case.*)

THE COURT:—Now, gentlemen, as you know, we are going to select alternate jurors under the statute.

(*The two alternates selected were Lloyd F. Hadeway, 26, assistant theater manager, and Frank E. McCrink, 41, electrician.*)

(*Thereupon, at 12:55 o'clock p. m., a recess was taken until 1:40 o'clock p. m. of the same day.*)

AFTER RECESS

THE COURT:—We are going to examine twenty more which I think ought to be enough to get to the alternates.

The Court addressed the same questions to a new group of prospective jurors.

Mr. Henry Weiss stated he had formed an opinion.

Mr. Hessick had formed an opinion.

Mrs. Etta Richwine had formed an opinion.

Mr. William J. Howard had formed an opinion.

Mrs. Martha Signor Bier had formed an opinion.

Mr. Lee D. Thren said he had pretty strong convictions but hasn't formed an opinion as to the guilt.

Mr. Thomas C. Hammett said Dr. Mattingly attended his brother's family.

Mr. Roland W. Beall knew Dr. Rogers Young and lived in the same small town with Dr. Rogers Young about 20 years ago.

Mr. Thomas G. Aycock knew Dr. Francis X. McGovern professionally. He operated on his son and attended him for about three months, about eight or nine years ago.

Mr. Hammett said Dr. Charles M. Hammett is a first cousin. Also Dr. W. M. Colton, former Dean of Georgetown Dental College, is his uncle, and also a friend of Mr. Leahy's.

Mr. Aycock has a sister-in-law in Public Health Service. THE COURT:—Have you ever had any relations with a doctor or anyone engaged in the practice of the medical profession which has in any wise prejudiced you against such a person or against the medical profession, so that you feel that you could not act impartially on the merits of the case?

Mr. P. Craig Jones:—Yes.

THE COURT:—Is any one of you employed by any executive branch of the Government of the United States? And I will add to that, is there anyone who was so employed since January 1, 1937, but who may now be disconnected? Either way, please stand.

(Four members stand.)

THE COURT:—The name, please.

Mr. Ralph F. Raymond:—Ralph F. Raymond.

THE COURT:—What branch or department?

Mr. Raymond:—I work for the Department of Agriculture.

THE COURT:—Agriculture. What is your position?

Mr. Raymond:—I am a photographer.

Mr. James R. Wannan:—Department of the Interior.

THE COURT:—What is the nature of your work?

Mr. Wannan:—Clerk.

Mr. Jesse C. Miller:—Jesse C. Miller.

THE COURT:—You are employed?

Mr. Miller:—Post Office Department.

THE COURT:—What is the nature of your employment?

Mr. Miller:—In connection with specification work on supplies with the Postal Service.

THE COURT:—Are you, or any member of your family members of any association or corporation, or have you or have they ever been members of any association or corporation which furnished or arranged for the furnishing of medical service?

Mr. William H. Sudduth, Jr.:—I have a sister who belongs to the Group Hospital Association.

THE COURT:—And the other gentleman?

Mr. Beall:—I belong to the Group Hospital Association.

THE COURT:—There are other organizations which fall under that same question. The next is the Good Will Fund; next, Edward A. Filene Good Will Fund; Health Economics Association. Or, generally speaking, of any Federal Credit Union, are you members or your families or close friends members of any so-called Federal Credit Union?

Mr. Wannan:—Your Honor, I am a member of a Federal Credit Union.

(At the conclusion of a conference counsel resumed their places at the trial tables, and the trial proceeded.)

The Assistant Clerk:—Jurors, as your names are called, please answer and take your seats at the jury box.

James M. Walsh.

Thereupon—

JAMES M. WALSH,

being called, took a seat near the jury box.

THE COURT:—Mr. Walsh, as you will recall, was on the other panel. He was the last one.

The Assistant Clerk:—Lloyd F. Hadaway.

Thereupon—

LYOYD F. HADAWAY,

being called, took a seat near the jury box.

THE COURT:—Gentlemen, I suppose we had better proceed and I will permit the Government to speak first.

Mr. Lewin:—The Government is content with the alternates.

Mr. Leahy:—If the court pleases, the defense will excuse Mr. Walsh.

The Assistant Clerk:—Mr. Walsh is excused.

(James M. Walsh excused.)

Thereupon—

HARRY J. JEFFRIES,

being called, took a seat near the jury box.

Mr. Lewin:—The Government is content with the alternates, your Honor.

Mr. Leahy:—The defense will excuse Mr. Jeffries.

(Harry J. Jeffries excused.)

The Assistant Clerk:—Frank E. McCrink.

Thereupon—

FRANK E. MCCRINK,

being called, took a seat near the jury box.

Mr. Lewin:—The Government is still satisfied with the alternates, your honor.

Mr. Leahy:—The defense is satisfied with the alternates.

THE COURT:—You may swear the alternates.

(Frank E. McCrink and Lloyd F. Hadaway were duly sworn as alternate jurors.)

THE COURT ADDRESSES THE DEFENDANTS

THE COURT:—Are all the individual defendants here at the present time?

Mr. Leahy:—I think Dr. McGovern is still sick in bed.

THE COURT:—Now I am speaking directly to the individual defendants.

The matter of the presence of you gentlemen individually throughout the trial has been the subject of discussion between court and counsel. The court recognizes that as busy physicians, during the course of the trial you may feel it necessary to absent yourselves in order to attend on some patient, and in order that your determination of matters of that sort should not be interfered with, because you alone can judge of the necessity of your absence under such circumstances, the court has suggested that it is willing that you should absent yourself. Speak to you individually, whenever, in your judgment, your absence is deemed necessary for attendance upon some patient, but I wish to suggest that you should be here as much as circumstances will permit. But I shall put no restrictions upon you, assuming that you now, each, individually, are willing to have the case go on in your absence, looked after, of course, by your counsel.

I would like you to stand, please, if you approve of accepting that suggestion from the court.

(The defendants rose.)

Mr. Leahy:—I have this suggestion to make, if your Honor please, before counsel for the prosecution begins his opening. I am advised that there was deposited with the clerk this morning a motion. Could we approach the bench for just a moment with respect to that?

THE COURT:—Yes.

(Counsel for the respective parties approached the bench and conferred with the court.)

(Counsel resumed their places at the trial table and the trial proceeded as follows:)

THE COURT:—I may say to the alternate jurors that for the purpose of attendance upon the court and listening to the evidence and proceedings and instructions of the court, you are part of the jury, just as much so as any of the others. So that you must follow things just as the other jurors do. As we go along I will give you more specific instructions if they are necessary; but at the moment the immediate thing before us is the opening statement of counsel for the United States in which they will outline in more detail the charge in the indictment and the evidence which they expect to produce in support of it, and of course I enjoin upon all of the jurors to follow it carefully so that you will understand the case.

Mr. Lewin:—Has your Honor any objection to the presence of witnesses for the Government during the opening statement?

THE COURT:—I will leave that matter to counsel. If counsel on either side prefer that witnesses be excluded, they will be; otherwise they will be allowed to remain in court. That of course applies to the Government witnesses as well as the defense witnesses.

Mr. Lewin:—The Government has no objection to any witness being present.

THE COURT:—If you wish, you can wait until after the opening statement and we can determine that tomorrow morning.

Mr. Leahy:—We might as well ask for the rule now, because eventually the witnesses probably will be excluded.

THE COURT:—Very well. Let the witnesses be excluded.

The Assistant Clerk:—All witnesses in the case now on trial, both for the Government and for the defendants, please return to this court room tomorrow at 1:30.

Opening Statement on Behalf of the United States by John H. Lewin

Mr. Lewin:—May it please the court, Mr. Foreman, and ladies and gentlemen of the jury, my colleagues here at the front table and I are Special Assistants to the United States Attorney General, and in the Department of Justice, and we have been charged with the duty of presenting to you the Government's side of this case. The time has now come when it is appropriate to make what is known as an opening statement of the facts which the Government expects to prove, and of the nature of the evidence by which it expects to prove those facts.

In order to correctly present my presentation of the facts I propose in this opening statement to avoid speaking extemporaneously, and will adhere rather strictly to written notes. I will caution you that of course my opening statement is not evidence.

The Grand Jury in this District brought these charges, and they are embodied in an indictment consisting of over 30 printed pages. The indictment itself is nothing but an accusation; and we for the Government undertake here and now this burden, to present before you evidence, oral and written, which we believe will convince you beyond a reasonable doubt that the substantial allegations of the indictment are true.

The indictment charges that the defendants committed a misdemeanor by violating Section 3 of the Sherman Anti-Trust Act, that section of the Sherman law which applies to the District of Columbia, in that they first concertedly boycotted and restrained business of a medical cooperative known as Group Health Association, Inc.; that they concertedly restrained the business operations of twelve private Washington hospitals, and that they restrained a number of doctors, those connected with Group Health Association, and doctors who otherwise would have been connected with it or would have consulted them in the free and lawful pursuit of their own calling. It charges that these defendants entered into and participated in a conspiracy to do these things over a period of approximately two years, beginning in January 1937, running continuously through 1937 and 1938 down to the date of the indictment, which was Dec. 20, 1938.

The defendants who are so charged in the indictment and who are on trial are:

(Here he listed the defendants.)

(After naming West, Fishbein, Cutter, Leland and Woodward.)

These five defendants are doctors, but they are not generally practicing physicians. The evidence will show that they devoted their time and energies as business men largely to the policies of this organization, the A. M. A., and to the business side of medical practice.

The remaining individual defendants, fifteen in number, were all practicing physicians and surgeons here in the District of Columbia. The evidence will show that they were all members of the defendant, The Medical Society of the District of Columbia, which is a local subsidiary of the A. M. A., and that they were active in its affairs, and particularly active in its affairs during the period of the conspiracy, and in the activities of that society, which are charged in the indictment.

It will be shown by the evidence that all of these 24 defendants, the A. M. A., the District Medical Society, the two corporations, the two associations, Harris County Association and the Washington Academy of Surgeons, and the twenty individual defendants acted and conspired together during a period of approximately two years, as I have described, to effect and bring about the restraints charged, the three types of restraint that I have mentioned, and that each of those 24 defendants took active part in furthering the complete scheme.

The evidence will reveal also that they were assisted by certain other members of the District Medical Society whom the Grand Jury did not name as defendants. They will be known as and shown to be co-conspirators with these defendants here.

The evidence will also show that these defendants induced and coerced the twelve private Washington hospitals, which are not defendants here, to join with the defendants as conspirators to bring about certain of these restraints.

It may be important to outline at this time a little more fully what the evidence will show about the A. M. A., its character, and the power that it possessed as the result of its great size, its importance and its activities in the medical world to impose the restraints which are charged in this indictment.

I have stated that it is incorporated; that it has these constituent and component local societies throughout the United States; that it has a membership of 109,000 doctors out of 169,000—all the doctors in the United States; that it publishes a weekly journal to subscribers numbering 95,000 people; that it maintains bureaus, councils and committees which concern themselves to some extent with medical economics, or the business side of the rendition of medical care. It also promulgates a set of rules which it makes binding on all of its members, including the members here in the District of Columbia who are members of the District Medical Society, and which rules embody some purely economic restraints upon the practice of medicine.

Although they are so interpreted, as the evidence will show, and so applied, these rules are given this innocent title and are called, "Principles of Medical Ethics."

Observance of these rules is enforced upon all the members in the first instance by the various local medical societies, such

as the District Medical Society for its members, and the Harris County Medical Society, down in Texas, for its members.

The evidence will show that observance of these rules is largely achieved because members are unwilling to suffer loss of prestige and ostracism which would result if they should be expelled from these societies, or otherwise disciplined for violation of these restrictions that are imposed upon them.

And so the evidence will show that the A. M. A. and the other defendants possessed enormous power to boycott and thus restrain any medical cooperative or hospital or doctor whose business methods of rendering medical care differed from the business methods favored by the A. M. A. and thus offered business competition to the A. M. A. or its members.

At this point let me turn to a description of the so-called victims of this alleged conspiracy and the activities of these victims which the indictment charges the defendants restrained.

The first victim was, of course, Group Health Association, Inc., a medical cooperative.

The next victims were the doctors who claim the right to pursue their callings unhampered by the defendants and who chose to serve on the medical staff of Group Health Association.

The next victims were those doctors who would otherwise have joined the medical staff of Group Health Association, or at least would have freely consulted with it in difficult cases but who were forced by the defendants to refrain from doing so because they were members of the District Medical Society, held by its rules, and the A. M. A., and because these doctors were in fear of those two organizations.

The other victims were the twelve private independent, so called, Washington hospitals, engaged in the business of caring for patients who need hospitalization and who would have welcomed such patients even though they might be members of Group Health Association or hospitals who would have extended to the Group Health doctors the same courtesy and privileges at these hospitals in order that Group Health patients might be treated in these hospitals by doctors of their own free choice.

Group Health Association was and is, as I have said, a consumer cooperative. It was formed by a group of Federal employees for the worthy purpose of putting into effect here in the District of Columbia a reasonable plan whereby they and their families and their dependents could obtain adequate medical care, including hospitalization, for less money, and whereby the cost of service could be budgeted and paid not in one great big lump sum, which might be disastrous to them, but prepaid in the form of small monthly dues to the cooperative.

I believe that an accurate statement of the issues requires me to state now that Group Health Association was in no sense a governmental agency. It was an independent private corporation. Although it was organized by employees of the Government, it was not a branch of the Government; nor was it sponsored by the Government. It had its merits and, since nothing is perfect, it may have had its imperfections. Nevertheless, whatever shortcomings it had, it was entitled to the protection of the law; and it is not sponsored by the Government in this case, except that the Government considers itself under the same duty to prosecute any persons, whoever they may be, who commit unlawful restraints as the Government is when such restraints are imposed upon any other business activity.

The plan of the Group Health Association was a simple one. It was borrowed from similar plans in other parts of the United States which had worked reasonably and successfully. The Government employees who initiated the plan were those employed by the Home Owners Loan Corporation, the H. O. L. C. It was later extended to certain of the other executive departments and bureaus of the Government.

The plan was first explained to their own credit union, which they operate themselves, where they deposited their money and borrowed in the H. O. L. C., by their personnel director, Mr. Raymond R. Zimmerman, who will be called to testify in this case. It will appear that the officers of the credit union thought well of the plan, because they took notice of the large amounts of money which the employees were borrowing from that credit union in order to meet medical bills; and the officials of the H. O. L. C. to whom these employees naturally submitted their plan before they put it into operation, also indicated, as the evidence will show, that they thought well of it, and they decided to encourage it, because they believed that as a business proposition for the H. O. L. C. more and better medical service available to their employees, preventive service and physical examinations and that sort of thing, as well as curative, might increase the efficiency of their employees and might reduce the loss to the Corporation from sickness.

Through the fall of 1936 and the early part of 1937 these plans were discussed and studied, and in January, 1937, at a mass meeting of all these employees, the employees voted almost unanimously to attempt to put the plan into operation.

A large number indicated their willingness to become members, and a consumer cooperative to operate the plan was duly incorporated under the Federal law, a private corporation, and given the name Group Health Association, Inc., and it was incorporated on February 24, two days after Washington's Birthday, 1937. It was purely a non-profit organization.

It undertook to collect from its members monthly dues. First, the dues were \$2.20 for an individual member, and \$3.30 for a family membership. Later it became necessary to revise those dues upward slightly. The individual membership remained at \$2.20; it never was changed; but the family membership was raised to \$4, and there were some additional small charges for dependents.

Out of this money so collected the Group Health Association undertook not to make any profit, but to defray the expenses of operating a modern, up-to-date clinic, centrally located where its members could get the benefit of the plan, to pay the salaries of a medical staff of doctors and the cost of 21 days of hospitalization in a hospital, where hospitalization would be needed.

Thus, with a few minor exceptions, which I will not note now, Group Health Association undertook in this way, cooperatively, to give complete medical care and to encourage its members to have regular physical examinations and other preventive treatments without any extra charge.

It proposed to employ a medical director, a licensed physician, and to leave to him, to his better judgment, the selection of the rest of the medical staff, and to leave to this medical staff complete freedom in all matters pertaining to the treatment of patients, unhampered and free from all interference in such matters by the laymen in the organization who were elected members for the purpose of conducting, without compensation to themselves, the purely business affairs of the cooperative.

It was contemplated that after the clinic was procured and equipped and was under way the dues collected would make the plan self-sustaining financially, but it was also realized that there must be some initial lump sum expenditures to procure the clinic and to procure the modern, up-to-date equipment that was to go into that clinic. Otherwise the establishment of the clinic would have to be deferred until these small monthly dues could accumulate in sufficient quantities.

I have said that the evidence would show that the officials of the H. O. L. C. manifested interest in this plan. They had made a study from monthly reports furnished the H. O. L. C.'s officers which showed that the H. O. L. C. was under the expense of \$100,000 a year for sick leave alone simply for its employees here in Washington—\$100,000 a year.

It will appear that these officials of the H. O. L. C. had acquainted themselves with the medical plans which many private businesses and industrial concerns had encouraged in the interest of efficiency of their employees.

The H. O. L. C. was a corporation created by an Act of Congress in 1933 to engage in the commercial business of lending money for the financing of homes and farm mortgages on homes. It paid its own way out of money which it earned in that business.

The statute, Federal statute under which it was incorporated, authorized it to determine its own expenditures, its own necessary expenditures, and the manner in which they were to be allowed and paid, without the provision of any other law governing the expenditure of any other fund. Accordingly, and under the statute, and the powers granted to the corporation thereunder, the officials of the Home Owners' Loan entered into a contract with that association in March 1937, whereby, on the one hand the H. O. L. C. agreed to make available absolutely to Group Health Association the comparatively small sum of \$40,000 and whereby in return for that Group Health Association undertook in this contract to maintain this medical service for the employees of H. O. L. C. and, in addition, to conduct physical examinations for the said employees of the H. O. L. C. and in addition to that to supervise nursing services provided.

Now, after the Home Owners' Loan became obligated to advance this \$40,000, which it agreed to advance part in cash and part in medical and surgical equipment which Group Health Association needed,—and I may say here that under the law the Home Owners' Loan was permitted in making purchases to get this at somewhat reduced prices through the Procurement Division of the Treasury,—I say after this money, this \$40,000 was advanced, this clinic was put into operation on Nov. 1, 1937. In other words it was incorporated in February; the contract was made in March; and the clinic opened in November 1937.

In May 1937 the trustees of Group Health Insurance Association, after making a previous attempt so to do, which the evidence will show was blocked and hampered by these defendants in order to prevent the association from acquiring a staff, engaged Henry Rolf Brown, a physician just about to retire from the medical staff of the Veterans Administration, engaged him to be the first medical director, and during the summer of 1937 he and Dr. Raymond E. Selders, a surgeon whom Dr. Brown had engaged for general surgery, occupied themselves in acquiring the necessary equipment. Dr. Brown selected at first three more licensed physicians and they were elected, after appointment, to work under the guidance and direction of Dr. Brown.

The evidence will show that this whole plan was sound and reasonable; that its details were widely conceived, and that under the circumstances, bearing in mind the vigorous opposition it encountered from the defendant these plans were, on the whole, well carried out. The business of Group Health Association was not itself to engage in the practice of medicine but was on the other hand to make the business arrangement for the provision of medical care and hospitalization to its members and their dependents on what is called a risk sharing prepayment basis. The risk sharing plan has some insurance features present in it in that you pay a limited amount or fee for which there is received this medical care where and while others may not have occasion to need or require that care although paying a similar amount.

Group Health Association paid its employees and medical staff ample salaries. It provided, where it was permitted to do so, hospitalization for its members and their dependents. The evidence will demonstrate the type of work and services performed by the general practitioners and specialists for the association. They had this advantage: They obtained by joining the medical staff and engaging in group practice under the direction of this medical officer the opportunity of familiarizing themselves with each other's experience and skill, and by making common use of the equipment, such as x-rays, they were able to and did avoid much unnecessary expense. The evidence will further show that the personal relationship, so important in the premises and which must exist between doctors and their patients, did continue to exist between the members of the association and the doctors on the staff engaged in treating and prescribing for them. The evidence will show that the lay officers, trustees, confined themselves to the business problems of the Co-operative and did not engage in any interference with the doctors in their rendition of medical services to the members.

Yes, the evidence will show that the Group Health Association was a worth while and needed experiment in the field of economics; in providing more efficient medical care at less cost, and in the manner in which the bill was to be paid. In short, in providing an easier burden to the patient in getting the medical job done efficiently. It was, as the evidence will show, an experiment which richly deserved, not the opposition which it got, but cooperation and assistance from so-called organized medicine, including these defendants.

There will be evidence of the need for providing medicine under such a plan, that is, at lower cost and with an easier way of paying for it, and it will be shown that this need was felt primarily by those in the lower income group, people who must be provided for on incomes of three or four thousand dollars, or less. It will appear that such people did not want clarity but on the other hand were such that if called on to pay at any time without warning the substantial amount necessary for medical care and hospitalization it might constitute for them a family catastrophe.

There will be evidence that these people could get as members of this group medical services they could afford to pay for at a price they could afford to pay, and the means of budgeting such expenses. The evidence will show that Group Health Association was designed primarily to meet such economic problems of just such people of such income status. And the evidence will also show that even the defendants themselves had recognized this need. That although they fully recognized it, it was after Group Health Association had embarked upon the solution of the problem, and only then, that the fear of competition from Group Health forced the defendants to attempt some similar enterprise of their own.

It is a fact that the qualifications for membership in Group Health Association were not confined to people of the low income group. The testimony will be that it was not thought wise for them to make any class distinction on that or any other basis, but it will also appear as a fact that over 83 per cent of those who joined by Nov. 1, 1937, and who had thus become interested in this organization were people of that low income

group; and it is also a fact that if Group Health Association had been destroyed, as the defendants tried to destroy it, such people would have suffered the most.

And now before I come to tell you of the hostile, unfair and oppressive treatment to be disclosed by the evidence which the defendants gave and meted out to this cooperative for nearly two years, let me outline briefly the nature of the evidence of the reasonableness and cooperative attitude which, on the other hand, Group Health Association and its officers and officials displayed toward the defendants, and particularly the District Medical Society. From the outset the sponsors of Group Health Association sought help and not antagonism from the local medical society. For instance, in the prospectus which first outlined the plan, and which was followed by one more in detail, both of which came to the attention of the medical society, there appeared this statement:

"It will, of course, be desirable to obtain the fullest possible measure of cooperation from the members of the medical profession of the District of Columbia. After the plan is launched the Medical Society of the District of Columbia will be invited to appoint a representative to sit with the committee which undertakes to establish the plan. It will also be requested to assign a committee of several physicians to advise the medical director of the plan of all relevant matters. The intention will be to solicit the advice and cooperation of the local medical society and to work with it to the fullest degree possible."

We will show that that expression of good will and willingness to seek its cooperation came specifically to the attention of the District Medical Society. Furthermore, it will appear from the evidence that as early as June 24, 1937, some of the officers and trustees, and the medical director, Dr. Brown, with the utmost good will, voluntarily attended a meeting of the executive committee of the District Medical Society at their suggestion and explained to that committee in detail the Group Health Association project; and at that meeting the Medical Director said frankly to them, "We will be glad to have our staff make application for membership in your society and cooperate with your society in every way we can for the uplifting of medicine. If you can help us select personnel we will be glad to take those recommendations, consider them and adopt them where possible." There will be evidence also that on three occasions this little Group Association, trying to get started, sought the cooperation of the society; that they approached the Society through its president, Dr. Neill, on several occasions and even offered him the surgeons'hip of the Group Health Association. The evidence will show that although Group Health Association would have preferred the active cooperation of the medical group in making this project a success, Group Health would have been happy, if that had been impossible, simply for the District Medical Society to let it alone. We will show that on this point one of Group Health Association's trustees asked the District Medical Society this reasonable question: whether it would be agreeable to the Committee of the District Medical Society, and the other associations, to let this program get started—this program as equally serious with us as their own was with them—in rendering an ethical service to patients; if they could not properly defer any action or decision with reference to us until we have lived a little while, and they had an opportunity to judge us and what we had done, not from the standpoint of what the other group has done, but from the standpoint of how we operate here. We asked them to simply delay any expression of opinion for the time being, we being free all the time to consult them; they being free all the time to consult us, working together cooperatively, each recognizing the other's ability and honesty, working it out on a plan satisfactory to this group here. Such an enterprise as I have described, the proof will show here, Group Health Association was; no more, no less. But the Government's evidence will also establish that in order for Group Health Association to succeed, in order to arrange for the best possible service to its members, at least three things were important and absolutely necessary. First, it must be free and unhampered in seeking to obtain qualified doctors for its medical staff and in retaining that staff after they joined. The right to be free and unhampered, the chance to be that. That is first. In the second place these doctors on its medical staff, specialists and general medical men, if there were any serious and difficult cases that arose in any doctor's practice, they must be free and unhampered in seeking consultations from specialists. Not the right to thrust themselves on an individual consultant, but the right to be free and unhampered in seeking such consultation.

Last of all, Group Health Association must be free and unhampered in seeking to obtain from the private hospitals in Washington, hospital accommodations for its members and

access to those hospitals for its doctors, so that these doctors could operate on and treat the Group members when they were hospitalized. In acquiring and holding a medical staff, in obtaining consultations with outside specialists, and in obtaining access to private Washington hospitals, Group Health Association did not require or seek any preferential treatment, but merely equality with the others.

And our evidence will show that the defendants realized that if they could exert their power in combination to shut Group Health off from acquiring these very reasonable necessities they might succeed in suppressing the competition, and might succeed in destroying Group Health altogether. And there will be evidence of other restraint. But we are prepared to show that the principal means adopted by the defendants to carry out their conspiracy to crush and destroy this competitor were:

1. To prevent any of the 800 or more doctors of the District Medical Society in Washington from accepting employment from Group Health Association, even if they wanted to do so, or from even consulting with any other Group Health Association doctors whoever they may be.

2. To obstruct Group Health in its efforts to obtain doctors for its staff from members of the profession, who were not even members of the District Medical Society.

3. To attack doctors who joined Group Health Association staff in order to induce them to resign, quit and abandon Group Health Association or, failing that, to punish them and discredit them in their profession in the hospitals.

4. To induce all, every one of the local private hospitals which were supposed to be independent enterprises, to join in this boycott of Group Health Association by refusing to admit Group doctors to hospital privileges in their institutions.

And you will be asked to contrast these drastic measures of opposition which the doctors carried out against Group Health Association, and its doctors—it is almost unbelievable but the evidence will establish it—with the totally different attitude manifested by Group Health Association seeking from the defendants merely their cooperation and good will. I shall outline the Government's evidence as to each of these four means adopted by the defendants.

First, I said was the boycott of the staff, preventing them from getting a staff, taking a staff, preventing them from getting consultants in different cases. As to the first of these, the staff and consultation boycott, the evidence will show that on March 3, 1937, just two weeks after Group Health Association was organized, the defendant District Medical Association amended its constitution so as to forbid all its members from having anything whatsoever to do with any clinic or with any doctors who were, for any reason, denied the approval of the District Medical Society. While it is true that this amendment was directed ostensibly against another clinic, a workman's compensation clinic known as the Crawford Clinic, it is true nevertheless that this amendment adopted in March, 1937, for the first time, two weeks after Group Health Association was formed, was shortly afterward invoked against Group Health. The amendment provides: That no member of the Society—and there were at least 825 of them—shall engage in any professional capacity whatsoever with any organization, group or individual, by any name called or however organized, engaged in the practice of medicine in the District of Columbia or within ten miles thereof, which has not been approved by the Society.

The Executive Committee is authorized and directed to prepare an approved list of organizations, groups and individuals by whatever name called or however organized, engaged in the practice of medicine in the District of Columbia, or within 10 miles thereof, and the same shall be kept in the office of the Secretary-Treasurer.

Now, in the debate leading up to the adoption of that amendment some of the members of the District Medical Society argued against it. They are not defendants here. One of them warned the others that if they passed it it gave the District of Columbia Medical Society the power to impose boycott on perfectly legitimate, legal clinics, and expressed the view that it was not an altogether wise thing to do to attempt to boycott that which is legal, a legal business, in this fashion. Notwithstanding that warning, the amendment was adopted and, once having deprived all its 825 members of their freedom by the imposition of this rule, the defendant, the District Medical Society, was in a position to prevent over 800 doctors practicing in Washington from either joining Group Health Association if they wanted to, or from consulting with any of its doctors, by the simple expedient of simply failing to put Group Health Association on that list. In June and July, or in June or July, 1937, the Executive Committee of the District Medical Society held its first series of meetings for the avowed purpose of discussing ways and means of combating Group Health Association. This appears in their minutes. At a meeting on July

ORGANIZATION SECTION

JOUR. A. M. A.
FEB. 15, 1941

12, it prepared and filed, pursuant to the amendment which I have just called to your attention, a list of all physicians and institutions furnishing medical care which it would approve. It was pointed out that the failure to put Group Health Association on this list would automatically forbid consultation by members of the association with members of the society. Accordingly, the defendants intentionally omitted from this private list the name of Group Health Association and any doctors whom it might have on its staff; thus the list became what is generally known as a "white list" and the effect was to blacklist all those who did not belong thereon.

The next step was to bring that home to all the members of the Society; those who attended the meeting and those who didn't, and on July 29, 1937, the defendant Dr. Conklin, the Secretary of District Medical Society, sent a letter to each of the members enclosing this white list and calling attention to the fact that the constitution of the District of Columbia forbade the members from having anything whatever to do with organizations and doctors not listed thereon. On the same day he sent another letter to all these doctors, directing their attention specifically to this provision of the constitution in his other letter, and specifically referred to an organization, referring to it as "an organization interested in gaining medical personnel." These letters constituted a direct threat that members of the District of Columbia Medical Society would be disciplined if they did accept employment with Group Health or consult with any of its doctors, and in August 1937, a man who until June 12, 1937, had been the chairman of the board of the Society wrote to the defendant, Dr. Hooe, telling members of the Society that they must be warned not to take position with Group Health.

The evidence will leave no doubt that this boycott was intentionally imposed. We shall offer the minutes of the various meetings held during the summer of 1937, and these minutes will reveal to you in great detail the plan which the defendants made for the imposition of this particular restraint. The local doctors here in Washington were assisted in this plot—they were large enough to do it themselves, but were assisted by the Chicago representatives of the powerful A. M. A.—I say they were assisted by the representatives of the A. M. A. who were specifically authorized to come down here to Washington to be on the ground, to participate and cooperate with the local defendants. The chairman of one of the subcommittees of the District Medical Society was advised by William Woodward, a full-time employee of the A. M. A., who is head of this Legal Medicine and Legislation Committee, "that the District Medical Society cannot go on with Group Health Association without violating what the A. M. A. considers principles of medical ethics."

Special committees were appointed to make recommendations for combating the Group Health Association, using that very word. One of the co-conspirators at an early meeting pointed out that one of the ways of attaining their objective was to discipline, and I am using his words, "Our own members." And he suggested that one of the weapons at hand—not reasonable persuasion but weapons at hand available was to forbid consultation with physicians doing this type of work. What type of work? The type of work I have described.

One of the committees, in a report to the executive committee, recommended four things that might be done to groups which were considered unethical. Another subcommittee, 1937, reported that Group Health Association is unethical, and the participation in it by any member of the Medical Society of the District of Columbia would render it amenable to disciplinary action by the Society.

There was the evidence that throughout the period of the conspiracy the defendants were vigilant in seeing that the members of the Society did not transgress. For example, in March 1938, two members of the group became seriously ill with heart trouble, and the group health doctor, who was attending them, felt the need, as any responsible physician would, of consultations with men who were heart specialists here in the City of Washington. He wanted to call such a specialist in consultation. This heart specialist was willing to consult, wanted to do so, but he was not permitted by the defendants to enter into the usual consultation at the bedside of the defendant. Oh, no, he was specifically instructed by Dr. Neill, the President of the Society, to examine these patients only in the absence of the Group Health Association doctor; not to enter into any consultation with any of the doctors employed by Group Health—and there will be documentary evidence of that. The evidence will show that another prominent Washington physician, also a member of the District Medical Society, but with some independence of mind, happened to be a personal friend of Dr. Brown, and because that doctor was observed having luncheon with Dr. Brown and conversing with him, and because that doctor accepted as his own private patient—he had a mask on—one of the members of Group Health Association and participated in a serious and dangerous operation of

such patient that doctor was proceeded against by this disciplinary committee of the District of Columbia. That committee, acting under the chairmanship of the defendant, Dr. Hooe, actually recommended that the doctor be subjected to discipline. Shortly after Group Health opened its clinic in November 1937, a young lady employed as a laboratory technician fell suddenly and dangerously ill of an acute internal hemorrhage requiring an immediate operation. Since no surgeon connected with Group Health had hospital privileges the doctor who diagnosed her case, and who had found her on the floor, rushed her to Garfield Hospital and employed a doctor, a member of the District Medical Society, to perform the operation. That doctor permitted the patient to remain a long time without attention, with her life in serious danger, while he haggled with the Group Health doctor as to whether he would be permitted by the Society to take the case, and agreed to perform the operation only after he was assured by the Group Health Association that he was entering the patient as his own private patient and not as a member of Group Health. After he got those assurances and not before, and all this time the patient in need of operative treatment, the operation was performed.

Mr. Leahy:—Without intending to interrupt you, are you referring to the Tew case?

Mr. Lewin:—No, I am not. I have no objection to giving the name. It is Mary Frances Stuart. I will mention the Tew case; I will get around to that.

Mr. Leahy:—I thought you would.

Mr. Lewin:—Moreover the evidence will show that the defendants were not content to deprive their own members of the right to treat members of the Association; their campaign was so venomous and so widespread that they succeeded in deterring other doctors from doing anything through fear of the defendants' displeasure and reprisals. At the outset Group Health Association sought to obtain as its first Medical Director a certain doctor who had just had a fine career in the Medical Corps of the United States Army. This gentleman approved heartily of the objectives of Group Health Association, and of its members. He approved the group practice and the advantages gotten from it, and he approved the prepayment scheme so people could get more for less money. He personally wished—he was free, willing, and twenty-one—he personally wished to accept the appointment but the opposition of the District Medical Society however was brought to bear upon him and he became convinced that he should not do it and went back to them after telling them that he would take the position, stating that disapproval by the District Medical Society would prevent Group Health Association from obtaining any available medical assistance. Thus, and this is important—for it will be borne out by the evidence, any adverse pressure which could or might be leveled at the medical staff of Group Health Association was directly attributable to the acts of the defendants themselves.

Now, let me take up the attack. This story gets worse and worse, the attacks which the defendant made upon Group Health doctors in order to induce them to resign from Group Health Association or, failing that, to punish them or discredit them in their profession with the hospital. On Nov. 1, 1937, Group Health Association announced a staff of five doctors. There was Dr. Brown, and four doctors he had just chosen to work with him. There was Dr. Selders, the surgeon, the doctor in charge of internal medicine, and—

THE COURT (interposing):—At any convenient time, Mr. Lewin, we will suspend and adjourn until tomorrow.

Mr. Lewin:—Well, I was just getting started on another point; this might be as good as any time to adjourn.

THE COURT:—Members of the jury, including the alternate juror. There are some observations which I want to make before we adjourn. It sometimes occurs in a protracted trial such as this undoubtedly will be, one which is likely to attract considerable public attention, that jurors who are selected to try that case are by order of court kept together and confined during the entire course of the trial. The purposes of that may be obvious to you. Among others, it is to relieve the jury itself of any embarrassment and unfettered and impartial attitude toward the case. Also, to relieve other parties and persons who in one way or another connected with the case might be embarrassed as a result of contact with such juror; also to avoid, as far as possible, any incidents arising which by their nature might be improper and thus break down all efforts that have been made by all the parties on both sides, all the expense to the Government and the parties, and all those contributions and participations in the trial to go for naught.

Now, I have the power to confine you in this case. It is one which should only be exercised by the Court when necessary, and depends entirely upon the circumstances, finally to be determined by the Court's discretion. I have decided not to confine you. I have great confidence that you will as jurors appreciate

the responsible duties which have been cast upon you, and that by your demeanor throughout this case you will remove any possibility, so far as it is within your power, of any incidents arising which could in any way embarrass you as jurors or prejudice the trial of this case. Some of you, I dare say, have been jurors before, and have a thorough understanding not only of the responsibilities of a juror, but I think also of the high honor and dignity of the office. I want to say to you very sincerely that in my own experience as a lawyer and as a Judge, much of it spent in courtrooms with juries, I regard the jury and each member thereof as occupying a position of honor, dignity and responsibility equal to that of the Judge himself. You are an integral part of this institution, set up by the sovereign power of the land to administer justice. You, in the trial of the case, are the supreme judges of the facts. You look to a Judge upon the bench to rule fairly and impartially. You expect him to keep his mind free of any sympathy, prejudice or influence which would in any wise affect the conscientious, fearless and fair determination of the matter upon which he is called upon to rule. A like responsibility rests upon you, and I want you to appreciate, and I want you every moment throughout the trial of this case to understand that these questions which were put to you and which you have answered resulted in your selection as jurors because on your solemn oaths you declared yourself in mind and heart thoroughly impartial and unfettered to undertake the trial of this case without any preconceived notion that would embarrass you or prejudice you in any wise. That means as you sit there now on the threshold of this case that you have assumed the same attitude of impartiality as you expect from a Judge, and I have confidence that you will maintain that attitude throughout the course of the case. It requires no particular quality of the mind or the spirit to assume and maintain a fair and impartial attitude. It requires only a conscientious determination to do so, and there is no reason, though you may lack the training which Judges may have, there is no reason why you cannot conduct yourself throughout this trial conscientiously with an impartial and fearless attitude. To do so be careful in your conduct. Be on your guard at all times so that at some loose moment you may not unwittingly embarrass yourself or the trial of this case. Be ever mindful of your responsibility and of the very high dignity and honor of your position. Especially avoid positions and situations arising as you go about and in and out of the courtroom which might invite a discussion of the case or which might throw you into a body where it is being discussed. Carefully avoid any discussion by yourself, even to members of your own family. You must determine the case upon your own judgment, so do not allow any suggestion from anybody else to creep into your mind, the result of which might be to prevent you from acting fairly and impartially.

Avoid reading of the case; doubtless there will be articles in the public press from day to day. Those articles are written by gentlemen who undoubtedly desire to make fair presentation of what occurs in Court, but they are written rapidly and sometimes without a just appreciation of the significance of the things which they purport to report, and so for one reason or another it may not be presented in the way in which it has actually occurred, or under the same condition as it occurred here and therefore may create a different impression. Now, you are here. You see and you hear this evidence. There is no reason for you to read about it any more than there is for me to do so. I don't have to. Neither do you, so I enjoin upon you very strictly not to read any printed matter of what purports to concern this case.

If at any time anyone approaches you in order to speak to you about this case, or if anyone does attempt to speak to you or influence you concerning this case, it will be your duty to report it to the Court at your first opportunity so the Court may take appropriate note and action.

And those things, I think, ladies and gentlemen, if you will bear them in mind continuously and without the Court constantly reminding you of them, I think will guide you along throughout the period of this trial in a way which will leave you at the end of it in the same fair and impartial state of mind as you are today.

Now, I am putting my confidence and my trust in you and I want you by your conduct and demeanor about this Court and away from the Court at all times to appreciate what it has meant to you for the Court to repose that trust and confidence in you. It has relieved you of what would have amounted to a virtual imprisonment for a long and indefinite period. Bear that in mind and that is because of the solemn oath you have taken which I am sure you understand and appreciate—because I am sure you realize your honor and dignity as jurors—it is because I am confident of your intentions and ability to maintain the honor and integrity of yourselves as jurors that I wish now

to permit you to go to your homes without any further admonition, but with the hope and confidence and trust which I have expressed and which I hope will be respected.

Now, as I indicated at the noon recess, the jurors will always be permitted to leave the courtroom first. When you leave I want you to disperse right away; get away from the courthouse at once, do not linger around. I will expect you here at ten minutes to ten each morning, unless I indicate an earlier time. You will be here and come into this room and assemble there and be ready to answer the roll call in your seats before I formally open Court, as the Clerk calls your name. Be here promptly at ten minutes to ten. You will now be excused.

(Whereupon, at 4:15 p. m., an adjournment was taken until tomorrow, Thursday, Feb. 6, 1941, at 10 o'clock a. m.).

FEBRUARY 6, 1941

MORNING SESSION

Mr. Baker:—Dr. Christie is much worried; he has come down with an attack of gallbladder trouble and is at this time unable to be present.

THE COURT:—That is all right. We can take that matter up during a recess, if necessary.

After summarizing his statement of the afternoon Mr. Lewin proceeded:

Mr. Lewin:—I told you that the defendants, as a powerful group, determined to destroy Group Health Association because they realized it was a business competitor of theirs, and they determined to destroy it by boycott; and then I told you of the principal means they adopted to shut them off from gaining a medical staff from any members of these large societies, and shut them off from getting a medical staff from even outside these societies by intimidating such members.

Now, let us take up the third of these means. The first was the staff boycott; the second the consultation boycott. The third means were attacks by the defendants on Group Health Association doctors, in order to induce them to resign from Group Health Association, or if they did not do so, to discredit them.

GROUP HEALTH ASSOCIATION

The Group Health Association had been incorporated in February, 1937, you will remember. Throughout the summer it had been trying to get its business together, and then its initial staff of five doctors, the medical director—the old gentleman whom the Association had just appointed, and who had just left the Veterans Bureau—Dr. Selders, a surgeon; Dr. Hulburt; Dr. Allan Lee, interns, general practitioners; Dr. Scandifio, who was a pediatrician, was the child specialist here in Washington; and a little later, a young doctor, Dr. Richardson, to make house calls upon the members who could not come to the clinic.

Dr. Selders was a man 45 years of age. He was a surgeon. He had practiced privately in Texas. You will begin to observe why the Harris County Medical Society comes into this case as a defendant. He was a member of the Harris County Medical Society in good standing, and therefore a member of this very American Medical Association, this Chicago corporation, which is a defendant here.

Dr. R. Stephen Hulburt had been engaged in the District of Columbia for a number of years in the practice of medicine; so had Dr. Allan Lee and Dr. Francis Richardson. They both came from private practice in Washington. Dr. Scandifio had been a child specialist here in Washington for a number of years.

Now if there was anything wrong with this staff, as I said yesterday, the fault is directly attributable to these defendants who were engaged all that time, all through that summer, in combating Group Health, and in an effort to prevent it from getting doctors. Up to this time they had been actively engaged in using their efforts—to use their own words—in combating it, although they didn't even know the names of all of these doctors. The evidence will show they had been anxiously awaiting the announcement of the doctors' appointments. The conspiracy had been in operation for many months and plans had been made to apply these boycotts against such doctors as would be appointed by Group Health Association, whoever they might be. On the day of the announcement, the A. M. A. agent stationed here in Washington telegraphed their names to the headquarters of the A. M. A. in Chicago, and immediately the defendant West wrote from Chicago—he is the general manager of the A. M. A.—he wrote to inform the District Medical Society here of their names, and pointed out that Drs. Lee and Scandifio were members of the District Medical Society and of the A. M. A. in good standing. So we had three members of the A. M. A. on that list, and he pointed out

they were in good standing. Three days later one of the prominent members of the District Medical Society engaged in this conspiracy wrote the defendant Woodward, the chief of the A. M. A.'s bureau of legislation, and this letter was passed on to the defendant West. In that letter the writer expressed the fear, his fear, that "this group"—the doctors who had identified themselves with Group Health Association "will probably become medical outcasts so far as we are locally concerned." You will see from the evidence how completely this prediction and intention was borne out. The evidence will disclose that attacks were made on each of the Group Health Association doctors, as I have named them, with the exception of this Dr. Brown. The attacks succeeded in the cases of three of these doctors: Dr. Lee, Dr. Hulburt and Dr. Richardson, internist, who were induced by pressure exerted by the District Medical Society to abandon Group Health, and Group Health Association thereby lost their services completely. But the evidence will also show that the objective failed in the cases of Drs. Scandiffio and Selders. These two doctors refused to be intimidated; they stuck to their guns and, as a result, disciplinary action was brought against Dr. Scandiffio here, and against Dr. Selders away down at the end of this long arm of the defendant corporation, the A. M. A., in Texas, in an effort to punish them. Now, as I said, two of them were members of the local staff, that is, two members of the staff were members of the District of Columbia Medical Society in good standing, namely, Drs. Lee and Scandiffio. The announcement of the appointment to the staff came on the first of November. On November 2nd, one day after that, one day after they joined Group Health Association, they were cited by Dr. Hooe to appear before his disciplinary committee, the disciplinary committee of the District of Columbia Medical Society, and were so cited solely because they had accepted positions with Group Health Association; and by that committee they were made the subjects of charges. Although they had as members reported the terms of their contract with Group Health Association and had done so as soon as the terms of their contract was reduced to writing, they were nevertheless charged with:

1. Having associated themselves professionally with a group of physicians who had not received the approval of the Society; and

2. They had not reported to the Society the oral understanding that they had made in November, or thereabouts, before the contract was reduced to writing.

As I said, this disciplinary committee was headed by Dr. Hooe, and he recommended that solely on these grounds these doctors be expelled absolutely from the Society. The two doctors were tried before the members of the Executive Committee of the Society, who purported to act as judges. The presiding judge at this trial was E. Hiram Reede; the associate judges included Drs. Neill and Sprigg, chairman of the Executive Committee, and Dr. McGovern, chairman of the subcommittee, which had already, during the summertime, recommended these boycotts against Group Health Association. He was one of the judges, and Dr. Conklin, the secretary who had written these letters enclosing the white list, on which the name of Group Health Association did not appear, likewise participated in the trial. Last, but not least, the defendant Hooe himself acted as a judge, although he was chairman of the committee that actually brought the charges.

ACTION OF DISCIPLINARY COMMITTEE

We will offer in evidence the stenographic transcript of those proceedings, and it will be disclosed incidentally that they conducted there a hearing, a so-called trial, which was unfair from first to last, and a perfect travesty on justice. The main purpose of the trial, as I have said, was to frighten these two doctors and thus coerce them into abandoning Group Health Association. The evidence will show those tactics succeeded in the cases of Dr. Allen Lee and Dr. Francis Richardson, both young men. After one session the latter had enough, and he was induced to recant and to abandon Group Health. Now, was he still punished for what he had done? Oh, no. Immediately thereafter the charges were dropped against Lee and he was taken back into the fold of the District Medical Society where, as far as I know, he still remains. But those threatening tactics did not succeed in the case of Dr. Scandiffio. He was young too, but he stuck to his guns. As a result however he paid a heavy price of complete expulsion from this enormous medical society here in the District and from the A. M. A. Dr. Hulburt, another of these doctors, did not escape. He was not even a member of the District Medical Society. Nevertheless, he was not immune from their attacks. Representatives of the District Medical Society exerted every effort to cause him to resign,

until, in November 1938, he quit the Association. After he left Group Health Association under that pressure, he was rewarded with hospital privileges, admitted to the courtesy staff privileges at Columbia Hospital, a privilege he had been trying in vain to secure, but which within a month after he quit Group Health he was accorded, and given access to that staff.

Little Dr. Richardson: he joined the Group Health staff to make these house calls. He enjoyed and had enjoyed the hospital privileges at Sibley Memorial Hospital, one of these twelve Washington hospitals; and in June 1938 he was approached by two members of the District of Columbia Medical Society and told that if he continued to serve on Group Health staff he would lose those hospital privileges. It was too much for him. The very next day he resigned from Group Health Association.

Now, Dr. Selders—just another incident. He was a member of the A. M. A., because of his membership in the Harris County Medical Society. He was in good standing down there in Texas. He had been a member for years. Two days before Group Health Association opened its clinic the long arm of organized medicine reached out. The defendant Conklin, again acting as secretary for this local medical society, wrote to the secretary of the Texas State Society informing him of Dr. Selders' employment, and the secretary of that society wrote back, requesting additional information so that charges of unethical conduct could be lodged against Dr. Selders. As a result of some further correspondence this Harris County Medical Society actually brought proceedings to expel him from the A. M. A. They never did expel him, but the evidence will show that the proceedings were instituted against him. And you are going to have access to the original records. The only charge against him was that he had associated himself with Group Health Association. For thus aiding and abetting these local defendants, and this powerful A. M. A., the Harris County Association, not the members individually, but the association, became a part of this conspiracy and was named as a defendant by the grand jury.

I now come to another serious means employed, the effort exerted to coerce and induce the independent hospitals to join in this conspiracy and themselves close their doors to Group Health Association doctors.

It is charged that the defendants conspired and coerced, or conspired to coerce these hospitals to boycott Group Health Association doctors from practicing medicine. Then, the defendants are charged with placing unlawful restraint on hospitals in the conduct of their own hospital businesses, and with employing these restraints on the hospitals as a further means for restraining and destroying the defendants' competitor, Group Health Association.

HOSPITALIZATION

Among the services that Group Health offered its members in return for the dues which they paid were twenty-one days hospitalization where needed, and without any additional expense; and surgical and medical treatment by Group Health Association doctors while they were in the hospital. Now they could have their own doctors if they wanted to; this is what they were entitled to. We will show that it was essential to the success of Group Health that it be free and unhampered in gaining access to these courtesy staffs of doctors practicing at these hospitals. I want to make absolutely clear to you that it is not the contention of the Government that Group Health Association, or any other clinic, has the unqualified right to thrust itself on any hospital it chooses and demand access thereto from any hospital, which acts independently and of its own free will in its desire to exclude such person or doctor. The evidence will show that Group Health and its doctors did not claim this right. They expected only equal opportunity in procuring these privileges. They merely took the position, and it is the position of the Government, that they had the same right as any other person, and that Group Health doctors had the same right as any other doctors, unrestrained and unhampered by any combination of these powerful defendants when they came to deal with each independent hospital; and further that these hospitals had the exclusive right to decide for themselves independently and separately, and uncoerced and unhampered by any pressure, what clinic or clinics they would recognize and what doctors they thought were of sufficient standing to admit to their hospital.

Now there are 12, and only 12 private hospitals here in Washington; there are some smaller ones. However, there were available to Group Health Association only the 12 which I will now refer to. Eleven of these are located within the city limits of Washington, and I will give their abbreviated names, to make it easier. They were Casualty, Children's, Columbia, Emergency, Episcopal, Garfield, Georgetown, George Washington, Homeopathic, Providence, and Sibley; and another hospital

which was also available, located out in Takoma Park, and known as the Washington Sanitarium. These 12 hospitals will be referred to in this case as the 12 Washington hospitals, without naming them. Each of these 12 hospitals is owned, not by the defendants but by independent corporations, and the control of the business affairs of each of these hospitals is entrusted by their corporate charters, not to the defendants but to a lay board of trustees, somewhat similar to the governing board of Group Health Association. Each of these hospitals has two kinds of medical staff. The first is known as the regular or attending staff; it manages the medical affairs of the hospital, as it should do. The second has no voice in the hospital affairs. It is known as the courtesy staff, and it is composed of doctors not on the regular staff, but who are permitted to treat their patients in that particular hospital. Except in emergency cases only those doctors who are members of the regular or attending staff, or who have been elected to the courtesy staff, are permitted to treat their patients there. If a terrible emergency arises they break down that rule. Group Health Association doctors did not even ask to be put on the regular or attending staff of that hospital; they did not ask for any voice in the medical management of the hospital, but the evidence will show that they did ask to be admitted to the courtesy staff. And the evidence will show that due to the defendants' conspiracy, and while it continued, all these hospitals failed to grant these applications, not to just one doctor of Group Health but to all doctors of Group Health; and such doctors of Group Health were excluded therefrom. And except in emergencies, the members of Group Health Association when admitted to these hospitals were denied treatment of their own free choice; that is, by the doctors of Group Health Association whom they wanted to treat them.

We will show you from the minutes of the District Medical Society how the defendants combined to exert this pressure on each one of these hospitals to cause them to exclude Group Health doctors. And we will not let it rest there. We will take you to the written records of each of these hospitals and show you how each one of these hospitals in turn had to succumb to this pressure and thus become co-conspirators with the defendants against the Group Health Association, and thus complete and make effective the boycott against Group Health Association.

CLASSIFICATION OF HOSPITALS

Now, before outlining in further detail what the evidence will show about the workings of that boycott I shall explain to you certain circumstances which gave the A. M. A. primarily and the District of Columbia Medical Society also the power to bend the hospitals to their will, and thus exercise control over those hospitals. The evidence will show that the power of the A. M. A., the big Chicago corporation, sprung primarily from its ability to withhold from any hospital certain all-important advantages in the matter of hospital intern training for residents. And the evidence will further show that the power of the District of Columbia Medical Society sprung primarily from that society's power practically to unstaff any hospital which the District Medical Society did not see fit to grant its approval to. Now, first, as to the A. M. A. power! It is customary for medical students, after graduation, to serve one or more years in hospitals for experience; they are called interns. They do it to gain more experience before they branch out for themselves. And when a medical graduate desires to specialize he may spend additional time in these hospitals as a resident, where he renders valuable services to the hospital but in return receives very little money. For a number of years the A. M. A. has undertaken to maintain a list of hospitals throughout the United States approved by it as qualified to give such training; and it is the only large organization in the country that does that. We will show that this approval, once acquired, is of immense value to any hospital, because if it is withdrawn that hospital suffers a great loss of prestige, and a black eye. Furthermore, since interns and residents will put in their time only in an approved hospital, one not approved cannot attract these men. In that event the hospital has to go out on the market and employ other doctors who have received their postgraduate training elsewhere.

The Government evidence will show that since A. M. A. has embarked on such an approval program it is essential to any Washington hospital not to be left out. Typical of such evidence is a letter which was written in August 1937, right here in this conspiracy, by one of the superintendents of these Washington hospitals to the defendant A. M. A., in which it was said that "No words can express my distress at the possibility of losing the approbation of our intern training school," and that such loss would prove a dire catastrophe to the hospital. And that ability to grant or withhold its approval at the will of its heads gave the A. M. A. power to impose such

conditions as it pleased in return for that approval. And we are prepared to show—this is not theory but actual practice—we are going to introduce direct evidence to show that the A. M. A., through its officer and agent, one of its full-time employees, exercised this power upon five Washington hospitals during the period of this conspiracy, and in furtherance of its objectives. Dr. Cutter is a full-time employee of the A. M. A. He is the secretary of the A. M. A., Council on Medical Education and Hospitals, and, as such, he is charged with the duty of recommending to the A. M. A. which hospitals shall be given its approval or denied its approval. Shortly after Group Health Association was organized, Dr. Cutter was informed of that fact by one of the members of his counsel located here in Washington, who wrote him at once, and with that knowledge in his possession, in March 1937, Dr. Cutter invoked a regulation of the A. M. A. that only members of the American Medical Association be admitted to the staffs of its approved hospitals, and made written demands upon the private hospitals in Washington here that they permit nobody not a member of the A. M. A. to be on any of their medical staffs. Those letters were expressed graciously and courteously enough but they were none the less a boycott. And during the summer and fall of 1937, Dr. Cutter succeeded in obtaining from four of the Washington hospitals—Colonial, George Washington, Georgetown and Providence—assurances in writing that they would comply with this demand of the A. M. A.; and in addition to these assurances from these four he received from another, a fifth Washington hospital in writing, a communication of its willingness to comply with this demand. We will show that compliance with this demand resulted in a situation where a doctor, although licensed to practice under the laws of the land, was not permitted to care for his own patients in any of these five Washington hospitals if, for any ground, reasonable or unreasonable, he should not be admitted to membership in the A. M. A., through one of these local societies, or if, for any other reason whatsoever, he should be expelled from the local society and, therefore, from the A. M. A. This demand of the A. M. A., and the responses which it got from these hospitals, operated directly to exclude Group Health Association doctors from these hospital facilities.

In addition to the activities of Dr. Cutter which I have described, we shall also offer in evidence testimony to show that the A. M. A. permitted the District of Columbia Medical Society to exert its pressure on the Washington hospitals to bring about the exclusion of Group Health Association doctors from these Washington institutions. The connection of the defendants Drs. Fishbein, West and Woodward—these full-time employees of the A. M. A.—in pointing out to the profession generally and to the members of the District of Columbia Medical Society particularly, the use of this weapon of exclusion, will also appear in the evidence. The defendant Fishbein is the editor of the A. M. A. Journal; the defendant West is the general manager for the A. M. A. The evidence will show that they were formally authorized to bring the Group Health Association's activities to the attention of the medical profession; and that acting under such authority they caused to be published in the A. M. A. JOURNAL of October 2, 1937, an article attacking Group Health in highly clinical terms; and that article was written by the defendant Woodward of the A. M. A. and was disseminated among these 95,000 members of the organization throughout the country. Special pains were taken, the evidence will show, to see to it that it got to the local doctors and to emphasize, among other things, these pointed statements with reference to Group Health Association. Particularly was attention invited to those members of the profession who were characterized as having medical services, to be by them in turn sold to others, and the fact that such doctors would be looked upon by the profession generally as being on the outer verge of ethical practice, if not altogether lost. As to those the communication stated, "It is not clear how they are to obtain qualified consultants or procure hospital services for their patients. In any event medical care in the associations would likely to be handicapped by difficulties likely to be experienced in obtaining the best consultants' services and hospital facilities," adding that those who had for sale their services to an organization like Group Health Association for resale, "are certain to lose professional status."

Now, if the true meaning of that paragraph is not clearly expressed we will show by other evidence that the other defendants expressly took note of its implications.

Now, let me return to a description of the evidence on those points against the District of Columbia Medical Society. The local district society had also set up machinery whereby it could influence the policy of the hospitals in Washington. Its constitution, which will be offered in evidence, forbids its 825 members from accepting assignments with or continuing to serve on staffs of any hospital not approved. By the simple with-

ORGANIZATION SECTION

JOUR. A. M. A.
FEB. 15, 194

drawing of its approval from any of these Washington hospitals, for any reason whatsoever, the local defendant, District Society, could unstaff any hospital it chose; and this policy to unstaff any hospital by the simple expedient of withdrawing its name from the approved list gave the District Society power to impose the unreasonable requirements it did impose and which the evidence will show that the District Medical Society and its members were quick to adopt and put into effect this suggestion that emanated from the parent body, the A. M. A., in Chicago. Just a week before the A. M. A. JOURNAL article appeared on October 2, 1937, at a meeting attended by six of the defendants here, a resolution was passed unanimously that the membership be admonished to read the entire article for their own information and guidance; and we will show that resolution offered by one of the defendants named in the indictment, and seconded by another, to the effect that a copy of this article be sent to each member of the Society as an enunciation of its future policy with respect to combating the Group Health Association. The evidence will show also that the author of that resolution told his associates that such resolution did express the policy of the society. And we will show that the communication to which I have heretofore referred stating:

"As to the ethical responsibilities of the Medical Society of the District of Columbia, and its members, the conclusion to be drawn from the policy as announced from the A. M. A. is inescapable"; and again referring to those combinations of doctors who sell their services to organizations for resale as being, and I am quoting, "certain to lose professional status."

And the evidence will show that the resolution expressly stated that the District of Columbia Medical Society is in full accord with the contents of the communication referred to; of such report, that is, the A. M. A. article, both as to the established facts therein set forth, and the implications to be drawn therefrom.

The evidence will further disclose that this feature of the plan, the hospital boycott feature which emanated from the A. M. A. to combat Group Health Association, merely confirmed and supported what already had been plotted by the local defendants of the District Medical Society. The proof will reveal that the formation of the Group Health Association had been discussed by the Executive Committee of the defendants at a meeting early in June, 1937, attended by a number of individual defendants, and that at that meeting one of the co-conspirators explained that the medical profession had two weapons; one, forbid consultations with physicians doing this type of work; and two would be to withhold approval from hospitals that would take in cases or assist the movement in any way. At a later discussion of the movement this same group were told that there were two ways available to combat Group Health Association: one, to discipline their own members who undertook to participate; and two, the possibility of restraining the hospitals through pressure on their staff.

During the summer of 1937, as I have said, these various subcommittees were appointed to make recommendations with regard to Group Health Association. One of these subcommittees, of which Dr. McGovern was chairman, and Dr. Hooe a member, presented a report in writing to the Executive Committee on July 12, 1937. We will introduce that report in evidence, including the statement thereof "The Medical Society by its present control over its members and through them of the hospitals, can adequately fight, if it is so desired, these small units. Full-time employees of the corporations could probably easily fail to be put on courtesy lists of the hospitals for one reason or another without the fact of the connection with the cooperative being even mentioned," and I still continue to quote, "In fact, any of the above methods would necessarily have to be camouflaged to the nth degree."

I have heretofore told you how the purposes of the A. M. A. and the District Medical Society were to be served through action by and pressure upon their own members; also how by the simple expedient of omitting the name of Group Health Association from the list which it approved, the white list, which it sought to obtain on a basis equally with others. I shall now point out to you that there is evidence that this white list was sent to each one of the Washington hospitals by the District Society and that it was intended to and that it did constitute a direct threat to such hospital of the consequences they might expect if they granted hospital facilities to Group Health Association or any of its doctors. But the defendants were not content with that. The evidence will reveal that the Executive Committee of the Society, attended by seven of these defendants, decided that the Society send a more pointed letter to each of these hospitals, directly asking these hospitals for

their cooperation. And this proposed letter, characterized by the defendant Willson as a veiled threat to the effect that if the hospitals did not comply the society would unstaff them, was sent. And we shall further show that in moving adoption of this letter the defendant Hooe moved that the letter warn the hospitals that if they failed to cooperate in every way they might not be on the approved list. The minutes of that meeting will show that while a discussion was underway relative to sending that letter one member inquired, and I quote, "If it was meant that the members of the Society would not be permitted to practice in the hospitals who did not subscribe? In other words, if they attempted to practice in the hospitals not approved whether the members of the Society would be bound to keep clear of such hospitals?"

The minutes further show that Mr. Sprigg, Dr. Sprigg, replied that that interpretation was correct. The minutes also reveal that some of the members thought that was too bald and in lieu of it the Medical Society at its meeting on November 3, 1937, attended by about 160 members, including eight of the defendants, determined to obtain this cooperation from the hospitals by less open and more facile methods. The minutes of that meeting will show that the Society formally adopted a resolution. And this documentary evidence will show further it was moved first by Dr. Willson and seconded by defendant Martel, and it was placed in this indictment by the grand jury in its return. This is the resolution:

"WHEREAS, The Medical Society of the District of Columbia has an apparent means of hindering the successful operation of Group Health Association, Inc., if it can prevent patients of physicians in its employ being received in the local private hospitals; and

"WHEREAS, The Medical Society of the District of Columbia has no direct control over the policies of such hospitals as determined by their lay boards of directors, except through its control of its own members serving on their medical staffs; and

"WHEREAS, Conflicts between the Medical Society of the District of Columbia and any local hospitals arising from an attempt to enforce the provision of Chapter IX, Article IV, Section 5, of its Constitution should be assiduously avoided, if possible, because of the unfavorable publicity that would accrue to its own members; therefore, be it

"Resolved, That the Hospital Committee be, and is hereby, directed to give careful study and consideration to all phases of this subject and report back to the Society, at the earliest practicable date, its recommendations as to the best way of bringing this question to the attention of the medical boards and boards of directors of the various local hospitals in such a manner as to insure the maximum amount of practical accomplishment with the minimum amount of friction and conflict."

We shall introduce evidence to show you that this hospital committee which was thus assigned the task of working out the best way of approaching the Washington hospitals as stated in that resolution, consisted of at least eleven doctors, each of them being a member of the District Medical Society and each of them having a position on the regular or attending medical staffs of one or more of eleven of these private hospitals; that is, on the staff that manages the medical affairs of the hospital.

The hospital committee was so constituted by the District Medical Society that it included a representative of the attending staff of each of these eleven hospitals, and the defendant Warfield was the chairman of the committee, and the defendant Young and Martel were members of it.

And I have stated before, the evidence will show Group Health Association opened its clinic November 1, announced its initial staff of doctors, Dr. Brown, medical director; Drs. Selders, Hulburt, Lee and Scandiffio.

I tell you that Lee and Scandiffio were members of the District Medical Society in good standing and members of the A. M. A. in good standing.

Dr. Lee and Dr. Scandiffio already had courtesy staff privileges at a number of the Washington hospitals.

Dr. Richardson when he came a little later had his courtesy staff conceded.

We shall show you the fact that Lee and Scandiffio enjoyed these privileges was specifically pointed out by the defendant Neill, then president, at a meeting held November 11, 1937, and when this was pointed out the defendant Yater suggested that the hospitals should be contacted and assurance should be given that no member would be allowed to practice there if he is a member of the hospital committee which it made.

And the first report of the staff of Group Health Association at that meeting and which was not strong enough, was reported back to that committee by the Society on the grounds that there seemed to be no assurance that the members of the staff of Group Health Association are not already or might not become members of the staffs of the hospitals.

The evidence will show you how completely succumbing these hospitals were to any such pressure from the Medical Society. On November 18, 1937, the secretary of the executive committee of the Georgetown University Hospital, an independent institution, wrote actually asking this Society whether the hos-

pital should accept Group Health Association patients; and whether the hospital's medical staff should consult with Group Health Association physicians.

We shall show you that at another meeting, December 1, 1937, the defendant Warfield, as chairman of the hospital committee, again reported for the committee, offering a resolution which was adopted then that the hospitals should follow the recommendations of the A. M. A., limiting their entire staffs to A. M. A. members.

And the evidence will show that the same defendant Conklin was again authorized to send that resolution—a copy of it—to each one of the Washington hospitals.

And he did so.

The evidence will reveal that all twelve Washington hospitals succumbed to this pressure of defendants; and that these boycotts inaugurated and fostered by the combination and conspiracy charged in this indictment were completely successful.

So effective were they that on March 28, 1938, the same defendant Warfield, reporting for his hospital committee, was able to announce triumphantly to the Society:

"Only three of the local hospitals, Columbia, Sibley, and George Washington, have not followed this recommendation of the A. M. A. All of the local private hospitals are cooperating fully with the Medical Society with respect to Group Health Association.

"At the present time only one of the local hospitals has on its staff lists the name of a physician connected with Group Health.

"This hospital does not revise its staff lists annually as do the other hospitals but it has assured the chairman of the hospital committee that steps have been taken to deny this physician hospital privileges."

Once the defendants succeeded in inducing these hospitals to adopt that rule that courtesy staff privileges would be denied any doctors who were not members of the A. M. A., the defendants' task, as you can see, in making this boycott effective, became comparatively simple.

All they had to do was to expel those members of Group Health Association's medical staff who were members of their Society, Lee and Scandifio, and to bring Harris County's Society into the conspiracy and get them to expel Dr. Selders. And to see to it that all applications that the Group Health Association doctors might make to any of these hospitals would be denied independent consideration of those hospitals but which would be turned down because of this agreement which they had arrived at with hospitals through their coercion.

You will recall that one of the subcommittees of the executive committee of the Society had concerned itself with Group Health Association and had reported as early as July 12, 1937, that any doctor connected with Group Health Association could probably easily fail to be put on the courtesy lists of the hospitals, for one reason or another, without the fact of his connection with the cooperative being even mentioned, and, in fact, any competitive methods would necessarily have to be camouflaged to the nth degree.

And this, the evidence will bear out, is exactly what happened.

We will introduce letters which the president of the Group Health Association, who will take the witness stand, wrote these hospitals in 1937, with the exception of Casualty and Washington Sanitarium—those two were replied to later telling them of Group Health Association—requesting that they admit the members of Group Health Association at the request of the Group Health Association medical director, and requesting also that the Group Health Association surgeon, Dr. Selders, be permitted to attend these patients while hospitalized.

And he enclosed with these letters a statement of Dr. Selders' qualifications and experience.

And later on similar applications were made by Group Health Association to Casualty and Washington Sanitarium.

And applications went later on to some of the hospitals to admit other of the Group Health Association doctors in addition to Dr. Selders. It wasn't just applying to him.

And Dr. Selders was given temporary privileges in normal obstetrics only, at Columbia Hospital.

Dr. Selders was a surgeon and he was given some of the temporary privileges in normal obstetrics only, temporary privileges for about a month for emergency cases at Garfield.

And Dr. Selders and some of the other Group Health Association doctors were permitted to treat a few Group Health Association cases at a few of the other hospitals.

Ten of the Washington hospitals to which Dr. Selders applied requested him to fill out formal application blanks giving his references, in addition to his education and experience.

When he did so, his application and references were referred by the hospital authorities to the attending medical staffs of those hospitals and their committees, which staffs and committees were composed almost exclusively of members of the District Medical Society and of the A. M. A.

And from the records of the various hospitals which we will offer in evidence, you will perceive that at least ten of the individuals charged as defendants in this case were members of the medical staffs or credentials committees of a number of these hospitals and acted thereon to protect their respective hospitals from admitting their competitors, Group Health Association doctors.

Dr. Selders' written applications, which he was asked to submit by ten of these hospitals, will be here in evidence.

And of these ten hospitals to which Dr. Selders supplied references, seven did not even bother to communicate with him.

And, the evidence will show that eight of the twelve Washington hospitals to which Dr. Selders applied for courtesy privileges formally refused to admit him there; four simply failed to grant his application. And Dr. Selders was never admitted to the courtesy staffs of any of these hospitals.

And we will offer in evidence the minutes of these various boards, staffs and committees of the hospitals and their correspondence, and it will be clearly revealed therefrom that this treatment accorded the Group Health doctors by all of these boards was directly caused by the pressure which these powerful defendants in this case exerted upon them, and by the opposition of the defendants to their competitor, Group Health.

And this situation was not confined to Dr. Selders. There is more evidence of this character relating to him than to any of the other Group Health Association doctors because he happened to be a surgeon of Group Health Association, and, as a surgeon, hospital privileges were particularly important to him. But let me make this clear, that the evidence will be clear that this hospital boycott was planned by the defendants before they even knew Dr. Selders, and that it was aimed not merely against Dr. Selders and not against Dr. Selders as such, but against the Group Health Association and any Group Health doctors who should request the privileges of treating Group Health patients in the hospital.

For example, one of these hospitals went so far as to give written instructions to its admitting officer listing all six of the Group Health doctors by name and stating, "These doctors are not to be allowed in at any time. And also use every precaution that no Group Health Association patients be admitted."

Dr. Allan Lee, before he was induced by the defendants to abandon Group Health by these charges that they brought against him, had applied for courtesy staff privileges at George Washington Hospital.

The defendant Washington Academy of Surgeons—I haven't told you much about them yet but that is coming along; it is part of the picture—this group of surgeons, on Dec. 8, 1937, two days before Lee was induced to resign, recommended to the George Washington Hospital that it disapprove Dr. Lee's application.

There is another instance, in the case of Dr. Lee.

When he joined Group Health Association he had courtesy privileges at the Emergency Hospital; on October 30, when he decided to join Group Health, he attempted to resign from the District Medical Society.

This resignation was not acted upon by the District Medical Society and later Dr. Lee withdrew it when they brought these charges against him, because he did not want to quit under fire at that time.

But, on November 1, just two days after he had presented his resignation to the District Medical Society, he received a letter from the Emergency Hospital telling him that his courtesy privileges at that hospital had been revoked.

Dr. Hower, while he was a member of Group Health Association, applied to the Georgetown Hospital where he had received his training, his own Alma Mater. He merely sought the privilege of treating an emergency case there.

And that case was the subject of discussion by the executive committee of the medical staff of Georgetown, and as a result of it, Georgetown adopted for the first time, a rule strictly defining what cases should be considered emergencies.

At Sibley Hospital the executive committee of the medical staff required an investigation to be made to ascertain whether Dr. Hulburt had any privileges there.

Dr. Hulburt also applied to Columbia.

Now, this is significant:

He applied merely for permission to treat a case of normal obstetrics. And, so long as he remained a member of Group Health Association, that application at the Columbia Hospital was held in abeyance.

But, when he resigned from Group Health Association under pressure in April of 1938, April 25, then, and only then, after he had left Group Health Association, was he rewarded with admission to Columbia Hospital. And his application there was granted in June of 1938.

ORGANIZATION SECTION

JOUR. A. M. A.
FEB. 15, 1941

That is not all. The rest of the doctors as well. Here in 1938 Dr. Halstead applied for courtesy staff privileges at a number of Washington hospitals.

He too was a member of the Group Health staff, up to the time the indictment was returned in this case, Dec. 20, 1938—no courtesy staff privileges at any of these hospitals had been accorded to him.

The evidence will show that other Group Health Association members received the same treatment.

It will show that some of the Group Health doctors, as I have said, although not accorded privileges to treat Group Health Association cases at any hospitals except in emergencies, did from time to time treat other cases during the hospitalization. But even in such cases these doctors recognized that they were there merely on sufferance and often the hospitals required that their connection with Group Health Association be conceded and that the treatment take the form of treatment by the doctor as his own personal cases, in these rare cases where he was permitted to do it.

And we will also in this evidence show examples of harsh, outrageous, impossible and unreasonable treatment accorded to the members of Group Health Association by a number of these hospitals.

Some of the patients taken to the Washington hospitals following automobile accidents or for serious operations, were turned away when they or their relatives insisted upon treatment by the Group Health Association doctors of their own choice.

They were forced to seek accommodations elsewhere. In one instance such expulsion from the hospital occurred after a Group Health Association member had been admitted as a patient, put to bed and given morphine, preparatory to operation, then denied services of a surgeon, Dr. Selders, because of his connection with Group Health.

She had to dress, in this dangerous condition, leave the hospital, get her own taxicab. Her friends were with her and they got it at the door. She was seriously sick and in this stupefied condition as a result of morphine.

In other instances Group Health Association patients in need of emergency care were kept waiting, their treatment delayed, and their health jeopardized, while the hospital authorities haggled and deliberated over the question of admitting.

And furthermore the evidence will show that one of these hospitals went so far in their boycott of Group Health Association members that it refused consistently to accept Association checks in payment of the hospital bills—made them get cash and bring it in there.

Even in cases where the members of Group Health were operated on not by Group Health doctors but as private patients of doctors not connected with Group Health in any way. Their mere association with Group Health made these hospitals refuse to accept any Group Health Association checks even.

WASHINGTON ACADEMY OF SURGEONS

Now, I promised to tell you about the part the Washington Academy of Surgeons played in this conspiracy. I have explained before that it is an unincorporated association of surgeons here in the District of Columbia.

And after Group Health Association opened its clinic, Nov. 1, 1937, we find the president of the Washington Academy of Surgeons inviting Providence Hospital to refer applications made to it for courtesy privileges, over to the Washington Academy of Surgeons for its recommendation, and the executive staff of Providence Hospital voted to do so.

And in the same month, November 1937, Georgetown Hospital also voted to refer applications for courtesy privileges over to the Washington Academy of Surgeons.

And, five of the twelve Washington hospitals to which application was made by Dr. Selders for courtesy privileges referred his application over to the Washington Academy of Surgeons.

And this Academy recommended to each of these five Washington hospitals that Dr. Selders' application be disapproved. Washington Academy of Surgeons supplied the hospitals with their excuse. It stated, however, no grounds or reason for such recommendations, and the proof will show that it deliberately acted in this way after the most inadequate investigation, if it can be called an investigation at all, of that applicant's qualifications or experience; and the written records of this defendant, Washington Academy of Surgeons, will be offered in evidence and will clearly reveal the true reason for this defendant's adverse action.

Notwithstanding the fact that the chairman of the Academy's committee on hospital privileges was expressly warned again by the secretary of Washington Academy of Surgeons not to permit Dr. Selders' connection with Group Health Association

to influence its decision, the executive council of the Washington Academy of Surgeons on Dec. 10, 1937, formally voted to give weight to what they term the ethics of the applicant. Poor ethics!

Ethics include violations of some economic restrictions of the A. M. A. known as the principles of medical ethics. Thus there is written proof that Dr. Selder's connection with Group Hospital Association objected to as unethical by the defendant American Medical Association, and which the defendant, the District Medical Society, as I told you yesterday, resolved formally to consider unethical, was the real reason for the defendant Washington Academy of Surgeons lending its aid to the hospital boycott against the Group Health Association doctors.

I shall now yield to my colleague, Mr. Kelleher, who I understand will more briefly state other elements of this case, which evidence to be presented to you will demonstrate are true beyond any reasonable doubt.

Additional Opening Statement on Behalf of the United States by Mr. Grant W. Kelleher

Mr. Kelleher:—May it please the Court, and ladies and gentlemen of the jury, what Mr. Lewin has said yesterday afternoon and this morning explains the evidence which we shall offer concerning Group Health Association and the alleged conspiracy of the defendants to prevent its operation. Thus it is this conspiracy here in the District of Columbia, and only this, for which the defendants are on trial. But while the alleged conspiracy for the District of Columbia has been for something less than two years, it had the country as a whole for its background, and for a prologue it goes back several years before the commencement of the alleged conspiracy.

THE BACKGROUND

Since you cannot understand fully the significance of what occurred here unless you view the conspiracy in its proper perspective, not as an isolated local occurrence but as a part of a national picture, we propose to show you what may be termed the background of the conspiracy.

In substance, we intend to prove that Group Health Association and similar organizations throughout the country were designed to solve a pressing social problem, that is, the adequate distribution of medical care; and that the efforts of the defendants to prevent the operation of G. H. A. in the District of Columbia were but the outgrowth and result of a nationwide long-range scheme of the defendant American Medical Association to stifle competition, economic competition, from such plans. We intend to present this evidence through the testimony of various witnesses and through numerous doctors.

The most important of the witnesses will be Dr. Hugh Cabot and Dr. Michael Davis.

Dr. Cabot, as many of you may already know, is one of the foremost surgeons in the United States. For many years he was a highly successful private practitioner in Boston. He has been professor of surgery at several prominent universities in the United States. Until quite recently he was a consulting surgeon at the famed Mayo Clinic. He is now medical director of an organization in Boston very similar to Group Health Association. And Dr. Cabot is and has been for several years a member of the defendant American Medical Association.

A second important witness on this phase of the case is Dr. Michael Davis, who is also an outstanding figure in his own field. While not a doctor of medicine but a doctor of philosophy, he is an expert on medical economics; that is, he concerns himself not with the professional side of the practice of medicine, but with its economic side, that is, so that doctors' services and hospitals' services are made available to men and women everywhere. Dr. Davis has been associated with various clinics, hospitals, and dispensaries, and for some time was a consultant on hospital organization. Since 1920 he has been a member of committees of two philanthropic foundations, the Rockefeller Foundation, and the Julius Rosenwald Fund, which committees have been engaged in extensive studies seeking to determine how to improve the distribution of health services.

Now these two witnesses, as I have said, will give you the background of the conspiracy. They will show you, in other words, the need for Group Health Association, the need for group practice, to reduce the cost of care; the need for prepayment to spread the cost of care. Dr. Cabot will compare for you the practice of medicine today with what it was some forty or fifty years ago, in his early years of practice. He will tell you that there has been more progress, more advances in the practice of medicine within the last fifty years, than there had been during the entire period of recorded history prior to 1890. In 1890 the amount of knowledge then available on medical matters

could conceivably be learned by a single man. Consequently most doctors were general practitioners, family physicians. And a specialist was rare except in a few fields. Diagnosis was largely based upon physical examination; observation of the doctor through his five senses, looking at the patient's tongue, holding his ear against the patient's chest wall. The equipment of a doctor was very simple and most of it could usually be carried in his little black doctor's bag. Knowledge of disease was extremely limited. For example, appendicitis was relatively unknown, and people were frequently said to go into a decline when, in fact, they were suffering from tuberculosis. Dr. Cabot will tell us that since 1890 there has been literally a revolution in the practice of medicine. And as a result of this revolution, practice today is far better developed, more scientific, more exact, than it was fifty years ago. Bacteriology has given us serums and vaccines for smallpox, diphtheria, and meningitis. Thanks to pathology, it is now possible to detect the presence of disease in the lung by examining thin sections of the diseased tissue; and the presence or severity of infection in the body can be determined. Drugs and their administration have become a science. Physiology has been revolutionized. Since 1890 physics has given us not only radium for the treatment of cancer and the electrocardiogram for the diagnosis of heart disease, but it has given medicine the most important single method of diagnosis in the entire field of medicine, the x-ray. Now, of course, this phenomenal progress in the last few decades in the diagnosis and treatment of disease is of the greatest value to the American people. And, at the same time, it is to the eternal credit of the man of medicine and science responsible for it. And I want to say here and now, that nobody in this case intends to, or could, detract from the esteem and credit due these men of science and medicine. But, in order for the people to reap the benefits of this progress, it is important that there be an adequate system of distribution. That is, that the medical services of the men and institutions who can give it be made more available to the men and women who need it.

You will see from the evidence in this case that there are many well informed men and women today who believe in good faith and after careful study that the distribution of medical care has failed to keep pace with the problems presented by the technical advancement to which I have referred; and that as a result there is a large body of American people today who either do not receive adequate medical care or are oppressed by the heavy financial burden of the care which it does receive. The evidence in the case will show that there are at least two reasons for this. In the first place, the progress which has been made has so substantially increased the cost of medical care that under the existing system of private practice by a single doctor on a fee-for-service basis, adequate medical care is beyond the economic reach of many people. The increased knowledge in the field of medicine today has made it really impossible for a single doctor to even attempt to grasp the entire field, or any substantial part of it. And, consequently, more and more doctors are specializing. The result is that the patient, at least in serious illnesses, needs the services of not a single doctor but sometimes two or more. And, of course, under the existing system, each doctor is entitled to and must be paid a separate fee. In addition, doctors of today need far more education than the doctor of yesterday required. Most doctors today spend eight years in medical school. And then from one to two years or more as interns or residents in hospitals. The equipment of the doctor is far more elaborate, more expensive, than was that of his predecessor. For example, he must have available a well equipped laboratory, which in turn requires a skilled technician. He must have an x-ray; he must have a means for determining blood pressure. And the end result of this increase in education and equipment which the doctor of today requires is that the investment and overhead of the doctor is far greater than it was forty years ago. And that, of course, is reflected in substantially higher medical bills for the patient.

The second reason lies in the fact that illness is as unpredictable as lightning. But unfortunately, unlike lightning, it strikes more than once in the same place. Dr. Cabot and Dr. Davis will explain to you this problem; and that may be termed the uneven incidence of illness. They will tell you that one family may go for years without a single serious illness, as many of you know, and that during that same period of time another family may be literally plagued with illness, so that the cost of care for the first family is negligible, while the second family may be bankrupt by medical bills.

COMMITTEE ON THE COSTS OF MEDICAL CARE

The evidence will show that this map of the adequacy of medical care received by the American people was the subject of comprehensive research by a committee of distinguished laymen and physicians known as The Committee on the Cost of

Medical Care. Dr. Davis was a member of that committee, and he will describe it and its activities to you. He will tell you that its chairman was Dr. Ray Lyman Wilbur, at present the president of Leland Stanford University, and Secretary of the Interior in President Hoover's cabinet from 1929 to 1933. He will tell you that this committee conducted a careful study of the medical care received by 8,500 families, embracing over 38,000 individuals. The income of these families varied from as low as \$1,200 to over \$10,000, so that the study represented a cross-section of the entire population.

This study, you will see, clearly establishes that there is a remarkable relationship between the amount of care which a family can afford and the amount which it receives, for that study shows clearly that as the income of the family studied went up, the medical care went up, but as the income of the family decreased the medical care which the family received also decreased; and this even though other studies showed that the amount of illness which any family has is not affected by the income which it receives.

The study showed that families in two or three lowest income groups, receiving less than \$3,000 a year, received far less of nearly every form of medical service, including doctors' bills and hospital bills, than the families in the higher income groups. The study also graphically demonstrates the disastrous financial effects of the uneven incidence of illness and how the burdens of sickness are borne by a very few people. The study showed that approximately one tenth of the families studied in all of the income groups paid \$41 out of every \$100 spent for medical care, but that six times as many people paid only \$18 out of every \$100 spent for medical care. For example, 5 per cent of the families earning between \$1,200 and \$2,000 a year paid as much for medical care as 80 per cent of the families.

What the solution is, however, is a difficult matter. I am trying to tell you now that we neither expect nor believe that the evidence in this case will show the complete answer to this problem. This much will appear, however: Group Health Association and similar organizations throughout the country are intended to and may to some extent improve upon the distribution of medical care. Group Health Association seeks to reduce the cost of care by combining together under one roof general practitioners and specialists in the various states; the effect of which is to give a member of G. H. A. the benefit of the joint knowledge of the group and, at the same time, to reduce the cost of the service of the group by eliminating the unnecessary duplication of equipment and facilities which would result if these doctors were engaged in private practice. It seeks to spread the cost of care by a system of periodic regular dues which entitles each member to complete medical care within reasonable limits, irrespective of the amount of care which the member requires.

As I said, there is no assurance, and there can be none, that Group Health Association is the answer to the problem, and no one in this case urges that it is. But when you have heard the evidence which I have summarized I think you will be convinced that the worthwhile objective of the Group Health Association to give that body of the American people which cannot afford medical care some form of medical care, makes it highly desirable that such organizations be fostered and encouraged. And it would be reasonable for you to assume, in the absence of other evidence, that the defendant American Medical Association which purports to be an altruistic, public-spirited organization of scientific men, would be the first to stimulate and encourage experimentation of this kind.

The evidence will show, however, that the American Medical Association has maintained a consistent policy of opposition toward such plans and has taken active steps to oppose in every way it has at its command such organizations throughout the United States.

I have already referred to the findings of the Committee on the Cost of Medical Care. That committee also made certain important recommendations which Dr. Davis will explain to you. He will tell you that 35 of the 48 members of that committee, representing a very substantial majority of the committee and including numerous of the outstanding physicians of the country, recommended that in view of the committee's findings concerning the inadequacy of medical care, persons with small incomes should organize into groups for the purpose of obtaining medical care on a prepayment basis from organized groups of medical practitioners; in other words, the groups should be on a prepayment basis.

I will tell you that a small minority on this committee, consisting of nine members, vigorously opposed this recommendation and took the position that prepayment plans are undesirable.

You will be interested to learn that two of the defendants in this case, the defendants Christie and West, were among those nine dissenting members.

ORGANIZATION SECTION

JOUR. A. M. A.
FEB. 15, 1941

We shall prove to you that immediately after those recommendations of both the majority and minority members of the committee were made public, the American Medical Association unqualifiedly opposed the views of the majority and fully adopted and approved the views of the minority. In editorials written by the defendant Fishbein and appearing in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION the report of the majority was violently criticized and its endorsers publicly excoriated, while that of the minority was undeservedly praised.

We shall show you that at its first meeting after the publication of the views of the Committee the American Medical Association, through its House of Delegates, the governing body, adopted a resolution endorsing the minority report which as I said, opposed group practice on a prepayment basis as expressive in principle of the collective opinion of the medical profession. On the other hand, we shall show you that in June, 1934, the American College of Surgeons, which consists of 11,000 of the most reputable surgeons of the United States, recommended that experiments with periodic prepayment plans be continued, because they furnish a reasonable expectation of providing for low-income groups more adequate medical care. One week after this recommendation of the American College of Surgeons was made public the American Medical Association adopted another resolution, condemning the College for its recommendation and demanding that that organization, that independent organization of surgeons, explain to the A. M. A. the reasons for its action.

FUNDAMENTAL PRINCIPLES ADOPTED BY A. M. A.
Finally, we shall show you that in 1934 the American Medical Association adopted general so-called fundamental principles to govern experiments to provide more adequate care to people with moderate means.

It will appear in evidence in this case that the American Medical Association insisted that any plan comply with its general principles if it was to be permitted by the American Medical Association, and that it insisted that all of its local societies enforce these principles.

You will see that one of these principles required that any plan embrace within it all of the qualified physicians within the locality to be served by the plan. Another required that the cost of medical service in any plan must be borne by the patient who could afford to pay at the time the service was rendered. Thus by the adoption of these "Ten Commandments" the A. M. A. made it impossible for organizations such as Group Health Association to comply, since of course such an organization was limited to the members of their medical staff, and since payment is not contemplated at the time of the rendition of the service, but is taken care of in the form of regular monthly dues. This evidence to which I have referred will serve to illustrate to you the hostile policy of the A. M. A. toward group practice on the pre-payment basis. But here and now I should like to caution you ladies and gentlemen that this hostility would not in and of itself be reprehensible if the A. M. A. had limited itself to peaceful persuasion in seeking to obtain adherence to its policy.

We shall show you, however, that the American Medical Association did not so confine itself, but that it exerted all of its tremendous powers to force doctors and hospitals throughout the United States to abide by this requirement.

POWER OF THE A. M. A.

At this time please bear in mind what the evidence will show concerning the power of the A. M. A.; how exclusion or expulsion of a doctor from that organization not only gives him a professional black eye but denies to him essential consultation with his fellows; how the system of approval and registration of hospitals makes it possible for the A. M. A. to obtain the ouster from the staff of any hospital approved or registered by it of any doctor of whom the A. M. A. disapproves for any reason whatsoever.

And we shall show you that it was the use of this power to oust from the United States experimentation with plans such as this, which furnished the pattern, the master plan of attack for the conspiracy in the District of Columbia.

We shall prove that doctors in Texas, in California, in Wisconsin were expelled from their local societies for participation in plans like G. H. A., and that in two instances the defendant American Medical Association, through its Judicial Council, approved the action of local societies by itself expelling these doctors from the A. M. A.

You will see from letters from two of the defendants in this case, the defendants West and Leland, that the action of the California Society was taken even though these two defendants knew that the doctors involved were, and I quote

them, "thoroughly competent physicians," and that the organization with which these doctors were associated, and I quote again, "delivers good medical service."

You will see that in all of these instances the defendants themselves admit that the one objection which could be taken to these doctors was that they were engaged in contract practice on a prepayment basis.

We shall go further than this. We shall show you that the use of the private hospitals in the District of Columbia to prevent the operation of the G. H. A. had its precedent in action taken by the A. M. A. to utilize its control over hospitals to prevent operation of plans in two other parts of the United States.

TRINITY HOSPITAL

The evidence will show that in 1935 the staff of Trinity Hospital in Little Rock, Arkansas, was engaged in supplying medical care to certain Little Rock citizens on a prepayment basis. On Sept. 9, 1935, the defendant Cutter wrote the superintendent of that hospital demanding an explanation, and when the superintendent, well aware of the hostility of the American Medical Association, in reply did no more than to admit the fact that the hospital was so engaged, the defendant Cutter, in a subtly-phrased letter, threatened to drop the Trinity Hospital from the register of the American Medical Association if it continued in this plan. The staff of Trinity Hospital persisted and refused to yield; and the following year you will see that the defendant Cutter made good his threat by dropping that hospital from the register of the A. M. A. because, as he wrote, "its contract plan makes it inconsistent for us to further endorse that institution."

In other words, that Cutter upheld action by the A. M. A. the effect of which was to disgrace Trinity Hospital in the eyes of the medical world.

MILWAUKEE MEDICAL CENTER

I have already told you that you would learn from the evidence in this case that certain doctors in Wisconsin were expelled from their local societies and from the A. M. A. for their participation in a plan like the G. H. A. The name of that plan was the Milwaukee Medical Center; and we shall prove that even while the expulsion proceedings of the local society and of the A. M. A. were pending against these doctors, the defendant Cutter invoked the resolution of the American Medical Association that doctors on the staffs of approved hospitals be members of the A. M. A.; he invoked that resolution as against all of the Milwaukee hospitals for the purpose of obtaining the ouster from those hospitals of the doctors associated with the Milwaukee Medical Center. And that resolution, incidentally, of the American Medical Association was adopted, according to the defendant Cutter himself, and I quote him, "to smoke out from the staffs of hospitals certain doctors who are objectionable and whom the hospital felt a delicacy about removing."

As I say, Cutter invoked that resolution against all Milwaukee hospitals, and they all yielded to that pressure except one. Mount Sinai Hospital at first refused to take the action which Cutter had recommended.

You will see from the evidence which we shall offer that in 1938, simultaneously with the conspiracy here in the District of Columbia, the defendant Cutter wrote the superintendent of Mount Sinai Hospital and told him that in view of the refusal of that hospital to drop the members of the Milwaukee Medical Center from its staff, he recommended to the Judicial Council of the American Medical Association that the hospital be dropped not only from the approved intern list but from the register of the American Medical Association. In this instance you will see that this threat brought prompt results. Within a few days the superintendent of Mount Sinai notified the defendant Cutter that all of the doctors of the Milwaukee Medical Center had been dropped not only from the active staff, but from the courtesy staff of that hospital.

This completes my side of the evidence which we shall offer to show the nation-wide opposition of the American Medical Association to group practice on a prepayment basis.

I come next to a consideration of the reasons for the opposition of the defendants to G. H. A.; and this, in turn, requires me to consider, first, the reasons which the evidence which we shall offer will show the defendants at times assigned for their opposition and the reason which the Government contends actually motivated the defendants.

In documentary evidence which we propose to offer you will see that some of the defendants urged that they oppose G. H. A. Why? Because, first, its set-up would necessarily result in a

reduction of the quality of medical service below that of the private medical practitioner, and, second, because G. H. A. was illegal.

So far as the first reason is concerned, I not only point out that the evidence will affirmatively show, first, that G. H. A., by being a purely voluntary organization, by permitting its members to drop the organization or to sign up at their own free will, gives to those members all of the freedom of choice which is either necessary or desirable; secondly, that the fact that the members of the G. H. A. are paid salaries instead of fees in no way affects the quality of medical care given by those members; and, thirdly, that the medical affairs of the Association are handled entirely by a medical staff, under a medical director, and without any interference whatever from the lay board.

QUALITY OF MEDICAL CARE

I am sure that when you have heard that evidence you will realize that the quality of medical care which G. H. A. gives to its members is at the very least the equivalent of the care which the average medical practitioner in the District of Columbia gives to his patients.

The second reason of the defendants, that is, that G. H. A. was illegal, requires some explanation by me. You will find from the evidence which we shall offer that the defendants at times urged early in the period of the conspiracy that G. H. A. was illegally organized, for one of two reasons: either, first, it was engaged in the practice of medicine without a license, or, secondly, it was engaged in the insurance business without having complied with the insurance laws of the District of Columbia.

Now, of course, ladies and gentlemen, whether Group Health Association is illegal and whether, even if it is, that constitutes a defense of the activities with which the defendants are charged, are matters of law for his Honor on the bench and not for you. But while you are not concerned with the legal aspects of this matter, you will be interested in certain circumstances concerning the successful efforts of G. H. A. to adjudicate this matter. This is so because we believe the circumstances will demonstrate to you that the defendants, in opposing G. H. A., were not particularly concerned with obtaining enforcement of the laws of the United States, but we insist they were using this claim to hide their real motive; that they entered into this conspiracy to suppress the competition of G. H. A. in the practice of medicine in the District of Columbia.

The facts which we shall show are briefly as follows:

Late in 1937 certain officers of G. H. A. became aware of the claims of the defendants concerning its illegality. They therefore approached the appropriate officials of the District of Columbia charged with the enforcement of the laws which were involved, and G. H. A. then determined to file suit to determine the legality of its organization once and for all. Accordingly, on Jan. 27, 1938, suit was filed in the District Court of the United States for the District of Columbia. That is the same court in which you ladies and gentlemen are now sitting. The suit was filed to determine whether G. H. A. was engaged in the practice of medicine or in the business of insurance, in violation of the laws of the District of Columbia. Mr. Justice Bailey, a colleague of Mr. Justice Proctor who presides here, presided in that case.

On July 27, 1938, Mr. Justice Bailey handed down a decision in favor of Group Health Association, holding, first, that it was not engaged in the practice of medicine; second, that it was not engaged in the business of insurance, and therefore that it was not violating any of the laws of the District of Columbia. In other words, he held that G. H. A. was a perfectly legitimate, legal organization under the laws controlling in the District of Columbia.

The evidence will show that the alleged conspiracy was in full swing and had been for many months prior to the filing of this suit in January 1938. This suit, as I have said, was pending for a period of six months. Now, if the defendants' justification of their activities on the ground of illegality was really in good faith, one would expect that the filing of this suit furnished a happy solution to their problem and that there would have been a cessation of their activity during the pendency of the suit and after that decision.

But what are the facts which we shall prove? We shall show you that on March 16, while this suit was pending, the District Medical Society formally expelled a physician from G. H. A. membership. On March 9, while this suit was pending, the defendant Harris County Medical Society filed formal charges against Dr. Selders looking toward his expulsion.

While this suit was pending the defendant, Washington Academy of Surgery, recommended to five of the local hospitals that they deny hospital privileges to Dr. Selders.

In the spring of 1938, while this suit was pending, Dr. Thomas Lee, acting upon the advice of the defendant Neill, president of

the local Society, refused to consult with G. H. A. Dr. Price concerning a patient with a serious heart ailment.

On March 28, 1938, while this suit was pending, the Hospital Committee of the Medical Society reported on the floor of that Society that all of the Washington hospitals were now cooperating against G. H. A. and that the only hospital which had a member of G. H. A. on its staff had given assurances that that member would be dropped.

That is some of the evidence which we shall offer concerning the activities of the defendants during the pendency of this suit.

Let us now look to the evidence concerning the defendants' activities after this suit was determined in favor of G. H. A.

It will appear in evidence that on July 28, 1938, the day after this decision, G. H. A. wrote a letter to all of the local hospitals calling attention to this decision and requesting that the members of its medical staff be now admitted to the local hospitals. What was the result? One hospital even went so far as to reconsider the matter and then deny Dr. Selders the privilege. Three of the local hospitals refused to consider any change. The rest of the hospitals ignored the letter of July 28.

Moreover, we shall show you that as late as September 1938, almost two months after this decision, a young doctor in New York by the name of Hammerly, who had been asked by Group Health Association to consider a position on its staff, wrote unwittingly to two of the defendants in this case inquiring whether A. M. A. would be offended if he took such a position.

We shall show you that the defendant Fishbein wrote this young doctor telling him that—

"It has been my observation that young men who depart from the established practices of the American Medical Association find it exceedingly difficult thereafter to achieve prestige among their fellows."

And we shall show you that the defendant West wrote this doctor and sought to discourage him from joining G. H. A. on the ground that G. H. A. was illegal—even though two months before, this court had held that G. H. A. was legal.

This evidence I think will show you that the reasons which the defendants gave at times for their opposition to G. H. A. were not the real basic reasons of the defendants.

What, then, was the real reason? We shall introduce substantial, competent evidence to prove that the real reason of the defendants was business and economic; that is, that they feared the economic competition of Group Health Association and that therefore they embarked upon and carried out this conspiracy to prevent G. H. A. from interfering with the financial return which the local defendants received from the private practice of medicine in the District of Columbia.

We shall prove to you that even before Group Health Association started, the defendants privately conceded among themselves that many people might view the plan as highly desirable, since it represented an effort by responsible, honest, public-spirited men to do something for their fellows if possible. You will see that many of the members of the local Society recognized that there was good reason to believe that G. H. A. had every reason to succeed; and we shall show you that it was this potential success of G. H. A., and not any defect or weakness in its organization, which became the real concern of the defendants, and they took action to block the operation of G. H. A. upon the theory that the success of G. H. A. and its expansion to include employees of other agencies of the Government living in the District of Columbia and in nearby Maryland and Virginia might seriously curtail the amount of private practice in the District of Columbia and thus reduce the financial return of the defendants.

You will see that one of the leaders in the activities of the Society, Dr. Mattingly, told the board of trustees on July 24, 1938, that if G. H. A. obtained its maximum enrolment it would result in the necessary exodus of a large part of the medical profession from the District of Columbia.

You will see that the defendant Woodward took the same view in an article in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, on Oct. 2, 1938, to which Mr. Lewin has already referred, and which, as you will recall, was written upon the specific authority of the board of trustees of the American Medical Association and under the direction of the defendants West and Fishbein.

After citing figures to show the proportion of the total population of Washington which G. H. A. might seek to withdraw from private practice in medicine, Dr. Woodward wrote that the effect of such withdrawal might withdraw persons able to pay for medical service and would materially disturb medical practice in the District of Columbia.

We shall also show you that this same defendant, Woodward, sought to enlist the cooperation of the Maryland and Virginia medical societies in the fight against G. H. A., principally with the argument that the personal economic interests of the doctors

in those states were at stake. He called attention to the fact that members of societies in counties immediately adjacent to the District of Columbia have an active personal interest in the matter. He urged these societies to cooperate with the local society of the District of Columbia because "certainly there is every reason why you should do so, not only from the standpoint of national interest but from the standpoint of local interest." And lest the doctors in those states should not understand the question, he warned them "against the competition with independent medical practice which will be set up by this Federal subsidy of a lay organization to buy and sell medical service to patients" in those states.

You will see from the minutes themselves which we intend to offer in evidence that the minutes are even more full of this matter of economic self-interest. You will see that on several occasions members warned that the income of doctors would be far less "if this Federal proposition goes through." Another urged the Society to take up the cudgels against G. H. A. because "we should look to the future. These plans all threaten the coming generation of physicians in their income."

You will see that the defendant McGovern urged action by the Society because he looked upon, as he put it, this organization "as coming in and interfering" with his business, because he intended to be in private practice for twenty years or more and that he did not intend, if it could be avoided at all, to permit this organization to come in and interfere with his work and income.

Ladies and gentlemen of the jury, that evidence which I have just summarized will show the keystone of the conspiracy, the economic purpose of the defendants to destroy legitimate competition in the practice of medicine in the District of Columbia.

FEBRUARY 6, AFTERNOON

The proceedings were resumed at the expiration of the recess, at 1 o'clock p. m.

Opening Statement on Behalf of the Defendants by William E. Leahy

Mr. Leahy:—When in the recitation of those facts which brought forth this prosecution I fail to preface before each statement that "the evidence will show this" or "the testimony will show that," will you kindly believe me when I say that the facts which I state will be based on evidence and testimony. The repetition of that assertion I eliminate only for the sake of not duplicating, and in the preservation of time.

In order that you may know just what the Medical Society of the District of Columbia actually and truly is, how it is constituted, how it operates and what its structure is, let me briefly tell you its story.

One morning at the stated hour of 11 o'clock, in an old tavern, then called Tennison's, on Pennsylvania Avenue, in this city, near 14th Street, were sixteen men. They met to form a medical association in the District of Columbia. There were good names among those men. Some of these physicians, still bearing the same names, sit opposite you as defendants. There was a Warfield among them. Other names you will recognize—McWilliams, McMahon, Hutchinson; and back in that dim day in our nation's history they met to form a medical association of the District of Columbia, because the people of the District of Columbia were being imposed upon then by quacks and sharks.

Sixteen or 17 months later, to be exact, on the 16th day of February, 1819, this association, now a defendant in this cause, received its charter from the Congress of the United States. It was the first scientific society which the Congress of the United States ever chartered. It was twelfth on the list of medical associations which had been formed, some while our states were still colonies and others shortly after the finish of the American Revolution.

New Jersey had its medical association as early as 1766; and notwithstanding the ravages of war which had swept across the colony of Massachusetts, those medical men, those doctors of that colony, were still thoughtful enough of the public health of their people and the service which they could render them, that in 1781, even before the surrender of Cornwallis, Massachusetts had its medical society.

In 1799 Maryland formed its medical society. This Medical Society of the District of Columbia is the natural heir to that, because four of those men who sat in that group that morning were from the State of Maryland, four were from Virginia, two were from Massachusetts, three had been born and raised here in the district of Columbia. And the charter under which the Medical Society of the District of Columbia first floated bears upon its face the names of Henry Clay and James Monroe.

Since 1819 the Medical Society of the District of Columbia has functioned for the good of its people and in the service of mankind.

The old charter, a bit antique in its language, nevertheless contains in one of its clauses the answer to the statement made as one which the prosecution asks you to take as gospel truth, namely, that these doctors, in this matter of G. H. A., were acting solely as economic competitors. That charter contains, as I said, the answer to it when it said in one of its provisions, back in 1819—

"Nothing in this charter shall be construed to give the Medical Society of the District of Columbia the right to control prices for the services which its members give to those who are sick."

Since that day the ethics to which every doctor in the District of Columbia has conformed have said that open competition is the life of the medical profession just as it is the most desirable element for the patient.

Now, what has the Medical Society as it exists to do with reference to the association commonly known and called the American Medical Association? Perhaps if I just briefly outline to you the general structure now of the American Medical Association you will see how this group, our own medical men, our own physicians, our own folks, fit into this scheme of the American Medical Association.

AMERICAN MEDICAL ASSOCIATION

The American Medical Association was formed almost a hundred years ago, to be exact, in 1847. It is an incorporated association, just as the Medical Society of the District of Columbia is an incorporated association. And may I join with my friends of the prosecution in saying to you that each is a purely voluntary association. No doctor on earth is compelled to join. No one coerces, forces or compels him to enter into association with his fellow doctors except his own free will and his voluntary choice. There is not a doctor in the District of Columbia who is forced to take out membership in the Medical Society of the District of Columbia. If he does, he does it because he wishes so to do, because it is only human among professional men as it is among many groups, perhaps some of you, to be associated in some organization—the Elks, or the Knights of Columbus or the Masons or what not—because you may like the association of good men; and professional men like the association of professional men.

And so this purely voluntary association is, in turn, a constituent member of the other purely voluntary association, the American Medical Association.

The American Medical Association, formed as it was back in 1847, is patterned precisely on our form of government; and if our form of government is the noblest experiment of man for the government of his fellowmen, then there can be no attack made upon the assertion that the American Medical Association is the most truly democratic voluntary association in the world today. There is no other patterned like it. It is the most perfect professional association for the advancement of the science and art of medicine which was ever conceived, because it has copied its structure after our own Federal Constitution.

And may I disabuse your minds at the outset of this covert insinuation, if not open statement, made by the prosecution, that the American Medical Association is in business. You have heard counsel say—in fact, I think both counsel said in their opening statement—that two of these officers were paid employees of the Association; they conducted the business end of the Association.

The American Medical Association is not in business. The District of Columbia Medical Association is not in business; and by no stretch of the imagination or description of human speech can either or both be denominated business corporations.

Throughout the various states of the United States, divided, as you know, into counties, we find the first of those groups which constitute the American Medical Association—the county association of doctors. They are gathered together in an independent unit, just as voluntary as any association can be. Not a single doctor in any county is compelled to join his county association. His membership is the pure voluntary choice of his own mind, his own preference and his own desire. But that group of men who wish to associate themselves together for the advancement of the art and science of medicine and its practice under ethical standards for the benefit of mankind, is the unit which reaches down into your home and my home, with your physician and my physician who is going to practice medicine ethically and under honorable principles which have existed ever since old Hippocrates, 460 years before Christ, practiced medicine under the supremacy of a civilization which has never been equaled in the history of time, when Athens was in her prime.

Ever since 460 years before Christ doctors have adhered to those noble, those inspiring and those lofty ideals which have made their profession, next to those who practice the profession of God himself, the most priestly and the most God-like under heaven.

This county association is an absolutely independent unit. The American Medical Association has absolutely no control over who belongs to it, how they came to join it, how they are elected. It has nothing whatsoever to do with the affairs of it any more than our Federal Government has to do with the government of Montgomery County or of Prince George County in the State of Maryland.

In order to further carry out the similitude of this organization to our own national government, just as the counties are bound together to form states, so these county associations are bound together into a state organization, so that each state in the United States has its own state organization. The state organizations are called constituent members. The county organization is called a component member; and then these various state organizations are all bound together in the American Medical Association.

THE HOUSE OF DELEGATES

In order that the American Medical Association may have a clear, accurate, definite reflection of what the practice of medicine should and ought to be for the best interests of the people of the United States as a whole it is provided that the American Medical Association shall hold what they call a meeting of their House of Delegates at stated periods. The House of Delegates is a meeting of those doctors who have been elected by their own county associations and state associations, and they all get together just as Congress does. But instead of their being called Representatives and Senators, they are all delegates of the American Medical Association gathered together in a congress to discuss—what? The standards of the profession, the ethics of a doctor; what the profession should do for the best interests of the people!

That is the only concern of the American Medical Association. It is the only concern of the District of Columbia Medical Association.

The only difference between our own Medical Society of the District of Columbia and the Harris County, Texas, Medical Association which you have heard described is that the Harris County, Texas, Medical Association is one of these component units I spoke to you about. It is one of those local county associations. The District of Columbia, of course, not being subdivided, but in itself as an entirety, has its own association which takes care of the entire District of Columbia.

Each unit governs itself. The District Society has absolutely no control of what the Harris County Medical Society shall do; the only unity being that every man who is a member of the American Medical Association becomes a member of the American Medical Association if he joins his county association, because a county association is, in turn, a component member of the American Medical Association; and the only unity existing between the members as individual members of the American Medical Association is this, that if they desire to become members—and it depends exclusively and entirely upon their own desire—then to remain members they must conform to those standards of right practice in the public good which 110,000 doctors out of 160,000 or 170,000 doctors in the United States have fought to conform to; and if a majority is supposed to rule a profession about which you and I know nothing, about which none of us except the doctors can tell, then certainly if a thundering voice of 110,000 have spoken it ought to be, even by the prosecution, accorded the credit of at least honesty of purpose.

Now we come to the individual defendants. Perhaps I should not omit from the discussion our own Academy of Surgeons, but really it comes into the picture so little that if we said nothing about it you would not fail to understand the trend of the testimony. It is just an academy of surgeons who in turn have voluntarily grouped themselves together in order to see to it that the practice of surgery upon the public shall be governed by proper standards in the public interest.

Now we come to the individual defendants. I am not going to rename them all. You saw most of them yesterday as they stood up to be identified, when you ladies and gentlemen were being qualified to sit here as judges of the facts. They are all men who have been members of their own Medical Society of the District of Columbia and of the American Medical Association for many, many, many years. They have practiced medicine under those ethics and standards for so many years that but few of them could not be the father of most of you on this jury. Their own medical association ethics have guided the conduct of each and every one of them; and blazoned forth in

the very first section of the constitution of the American Medical Association is that the standard of the practice of medicine by doctors in these United States shall be guided by the principles of rendering service to humanity, and let what you get for it be second. The constitution will be read to you, and that has never been changed.

Something was said to you in the opening statement about the standards which we call ethics, and the imputation was made, which requires an answer, that we autocratically fixed those standards, and that if one does not conform to them, then the societies, from the top down to the component county societies, seek to destroy a person who fails so to conform.

The plain answer to that was given also, but perhaps you did not get it. There are approximately 60,000 doctors in the United States who do not conform to those standards. There are 60,000 doctors against whom the American Medical Association has never moved, and those doctors did nothing contrary to the public interest.

In the District of Columbia there are 2,000 doctors. Eight hundred and twenty-five belong to the District of Columbia Medical Society. There are then approximately 1,200 doctors in the District who do not belong. I do not think that even the prosecution can produce a theft or a murder or an assault and battery committed upon one of the doctors who does not belong to the Society. It goes back to what I told you it is—a purely voluntary association of honorable men, men who have worked their lives down to the point now where the sun is sinking, in the honorable practice of a profession which they thought should never be practiced by any man or group, no matter by what high-sounding name it may be called, whether it be by way of experimentation or accomplished fact, which practices or advocates the practice of that profession in a manner contrary to the best interests of the patient and the public good.

PRINCIPLES OF MEDICAL ETHICS

The American Medical Association has had that standard of ethics ever since it was organized. The American Medical Association had little to do with the formulation of these ethics. It was done for them years and years ago, as far back as 1803 when an English physician named Thomas Percival formulated the ethics of the medical profession for the College of Surgeons in the city of Manchester, England. Those ethics were formulated on the old oath of Hippocrates, and they have come down through the ages, through civilization dead and gone, through millions of people who have tried experiments like this G. H. A., and they have always proved the only safe standard under which medical care can be adequately distributed in safety to the public and the patient.

Let us briefly advert to Group Health Association, Inc. You have heard it called in the opening statement variously as a consumer cooperative—names you never heard of until about 1932, perhaps. You have heard the practice of medicine described as the "distribution of medical care"; and you will find that along about 1930, and particularly after the crash of 1929, among certain members of the public who thought that by some, as they thought, new experiment they could cure the ills of all humanity, there sprang up these various new notions of social philosophy, and they tagged them with a new name. Perhaps you have heard it. They are new ideologies but these new ideologies came into clash with the ordinary method under which you and I were born and lived, and they thought that in order to cure the social evils of which this country was suffering, and the world itself was suffering, they ought to destroy the old order entirely and start all over again.

There was no indication in this experiment of the Group Health Association just what would happen after they had destroyed the practice of medicine as it had progressed in this country ever since the early days. But that was not their objective. Their objective was to impose upon the medical profession of the District of Columbia this social economic experiment, and if the medical profession, who in all this world are the only ones who can judge whether medicine is being practiced properly or not—if the medical profession did not like it, they could lump it and get indicted.

This Group Health Association was not the spontaneous outburst of these employees of H. O. L. C. in the "low income brackets." They love to use those terms—"low income brackets," poor people who cannot afford the expense of illness and who suddenly find they are suffering with an illness which sends them to bankruptcy and breaks up their homes. It did not rise in that way. The Group Health Association, Inc., was one of the most carefully conceived schemes which has ever been put into operation. It did not rise in the Home Owners Loan Corporation at all, but it had risen under the

ORGANIZATION SECTION

JOUR. A. M. A.
FEB. 15, 1941

advice, counsel, inspiration, and instruction of certain groups who again styled themselves under a catch phrase—a "foundation" or a "fund."

The background of this alleged conspiracy was just rehearsed to you this morning. In that background the prosecution was careful to omit those experiments of a similar character to this which had been tried and found woefully wanting, when either the foundation or the fund which sponsored their inception and their experimentation withdrew funds which were necessary for them to continue to exist, or they simply died "a-borning."

They told you this morning that since 1890 the science or art of medicine as practiced in the United States had progressed more rapidly than in any other period of known time. Had the prosecution been fair it would have told you that those advancements in the practice of medicine were due to the efforts of the American Medical Association to prevent the destruction of that progress by the quack and the charlatan who advertised his wares in such language as Group Health Association advises to catch the public with the phrase—

"You can budget your sickness expenses. You can pay so much a month and get adequate medical care." You can pay so And you will find that the American Medical Association has been so constantly on the alert for the advancement of the science and art of medicine that today young doctors training to become the doctors of tomorrow no longer have to go to Vienna or Germany to practice and learn, but the doctors of Germany and Vienna come to the United States. Today medicine has been brought to the highest standard ever known in the history of the world; and the prosecution says they cannot deny that statement. Medicine and its practice has been under the control, direction, advice, instruction, and careful preservation by the American Medical Association and its constituent and component societies.

COOPERATIVE LEAGUE

I told you that this scheme was not one which spontaneously burst like the inspiration of some poet or musician, so that out of the brain of some one came this unusual plan. Back in 1919 a man named Edward A. Filene established what he called a Cooperative League up in Boston. In 1922 the name of that league was changed to the Twentieth Century Fund. Edward A. Filene's perhaps closest friend was John H. Fahey, chairman of the board of the Home Owners Loan Corporation. He was so close a friend that he is executor under Mr. Filene's will. Mr. Filene died in 1937.

The Twentieth Century Fund had a department which was called the Medical Economics Department. That fund was well financed. It had back of it 150,000 shares of Filene's store, which paid \$1 a year dividends. It had \$500,000 in good bonds and stocks. So that when the prosecution points you to the power of the American Medical Association and the power of the various constituent and component societies thereof, I ask your attention to the testimony as to the power behind Group Health Association.

TWENTIETH CENTURY FUND

That fund was a corporation. Its name, after 1922, was the Twentieth Century Fund. It was a hundred years ahead of you and me—or thought it was. It was engaged in the study and investigation into, and the recommendation for, various, as they said, forward-looking projects; so that the American Medical Association, which had the benefit of the experience of a hundred years, the District Medical Society which had the benefit of the knowledge, the training, the advice, the cooperation and association of its members since 1819—they were Tories, obstructionists, if they did not believe in what the Twentieth Century Fund proposed.

Now, was this Twentieth Century Fund, in the department of Medical Economics, composed of doctors who knew something about the practice of medicine? No. R. W. Rickard had charge of that. And then in the fall of 1936, to be exact, on the second and the 30th of October of that year, there seemed to have come into the Twentieth Century Fund a desire for renewed activity in the shape of its investigation into and recommendation for the practice of medicine in the United States.

There had been formed theretofore another corporation called the Health Economics Association. So the Twentieth Century Fund revamped the charter of that corporation and put Mr. Rickard in charge of Health Economics Association, Inc., as its executive vice president.

Then, at the same time, they organized another corporation and gave it another fancy name, calling it the Good Will Fund.

HEALTH ECONOMICS ASSOCIATION AND GOOD WILL FUND

Health Economics Association, Inc., and the Good Will Fund are godfather and godmother to Group Health Association, Inc., that we have been talking about, because in October Mr. Penniman, the name that you have heard mentioned heretofore, made what he thought was a brilliant and a sudden discovery hitherto unknown to mankind. He had come from outside the District of Columbia and was director of personnel with the Home Owners Loan Corporation—and it almost makes us here in Washington smile—because he suddenly discovered that Government clerks take sick leave. So he started to figure out what sick leave cost the Home Owners Loan Corporation. That is what he said. And he went before the board of the Home Owners Loan Corporation with the remarkable discovery that as to how much it would cost the Home Owners Loan Corporation on account of this sick leave. He figured out up to \$500,000. It should have developed into a hospital instead of an organization! But at all events he went to the board and asked the approval of the board for the organization of some group in Home Owners Loan Corporation in order that some members and employees of Home Owners Loan Corporation might be guaranteed good health by some kind of a plan under which, by payment of so much a month, they would get everything they needed in the shape of medical care.

Then, too, he found that as in all government departments there was an excellent thing, an emergency room. You find them in almost every office in the District of Columbia of any size, for the purpose of taking care of an employee who becomes ill on the job. If he needs emergency care there is a place where the employee needing that care may be taken.

So he also represented to the board that that business of taking care of the emergency room, and the nursing staff, and what not, in Home Owners Loan Corporation could all be swallowed up in this new theory—the Group Health Association. It is no more new than dozens of others which had fallen by the wayside, because economically, as the testimony will show, it is unsound; it cannot give adequate medical care; it interposes between the patient and the doctor the direction of a lay body who know nothing about the practice of medicine and will only hinder and throttle any doctor who is attempting to take care of his patients. It interferes with the free choice of physicians. You can see that, because the members take what is provided for them, to wit, the doctors on the staff.

At that time Penniman reported that he had studied somewhat and had sought the advice and counsel of someone of those who had given attention to this kind or sort of group, the "herd" practice of medicine. And of course it was the Twentieth Century Fund. They had been dabbling in theories for years. Rickard, a paid employee, had been heading up the department under Group Health and was now the executive secretary of Health Economics, and he gave for the benefit of the employees, as he thought, his knowledge and his experience.

Now, on the point of cooperation the testimony of the defense will be directly to the contrary, and will prove every word of what I say.

It is only fair to assume that if someone is going to organize a group of employees in order to obtain for those employees adequate medical care, so that an employee in case of illness shall receive proper treatment—it is only fair to assume that someone ought to be called into consultation who knows something about how to provide adequate medical care.

GROUP HEALTH ASSOCIATION, INC.

This concept of Group Health Association, starting as it did in October of 1936, never had room for one word of consultation, advice or instruction from a single medical doctor in the District of Columbia. This is the association that the prosecution said this Group Health Association desired to cooperate with; and the testimony will show that the Medical Association of the District of Columbia never heard of Group Health Association until the coming of an event which I will tell you about later. Group Health Association never asked any single doctor in the District Medical Society whether it was wise or unwise, efficient or inefficient, ethical or unethical, medically sound or unsound. The trouble with G. H. A., as I will show you when we come to the analysis of its whole structure, is that these men who headed it up were economic theorists. You can't sell medical service as you sell baked beans or a package of cigarettes over a counter. The practice of medicine has in it that intimate relationship between the patient and the doctor, the absolute confidence of the patient in his doctor, so that when the doctor comes in to make a diagnosis of the patient's illness, the patient

unhesitatingly gives to the doctor full and complete and most confidential information, knowing that it will never be disclosed, but upon which the doctor must act in arriving at an accurate diagnosis.

Therefore the body which now they say they wished to have assist them, the Medical Association of the District of Columbia, the testimony will show was never consulted in one single particular with reference to the formation of Group Health Association. The fact of the matter is—and is not this strange—the fact of the matter is that after they had been working on this thing for about two months they got out a beautiful little brochure which was all decorated up with pictures of pretty nurses, and the doctor standing over the patient at the bedside, and on the outside it said, "For confidential information. Not to be distributed to the public."

This is the organization that wanted to cooperate with the doctors.

The man whom Rickard got to assist was a doctor in Chicago who has been advertising in newspapers who headed up an organization that the Supreme Court of Illinois declared to be illegal and told him to quit doing it. That is Brochure No. 1. I don't think Group Health knows we got it, but we got it.

They were by this time working along so that they had this organization pretty well planned out on paper. Not one of us knew anything about it. The American Medical Association, the Harris County Medical Association, the College of Surgeons, the District Medical Society—they did not know anything more about this than you did before you heard about it yesterday and today.

They had this Army officer who, the prosecution told you, had agreed to head up this Group Health Association as its medical director and whom, he said, we persuaded to refuse to become medical director. Penniman, Zimmerman and others were down here for months keeping away from the Medical Association any knowledge whatsoever that they were going to spring this organization whose purpose and objective was aimed straight at the heart of the practice of medicine as it had been known for over a hundred years in this country.

We did not have a thing to do with either General Ireland's or Colonel Jones's refusal to take the job as Medical Director of that organization. How could we? We did not even know it existed. We did not even know it was in contemplation. Somebody must be mistaken, because the evidence which we have as to why General Ireland did not become Medical Director of that association is that he asked the Colonel to make a careful investigation of what sort of an association this was. Others had been trying this all over the United States. This was not new, this notion of group health. The report came back that it was an entering wedge into State-controlled medicine, and he said, "We dropped it like a hot potato."

That is why they did not get General Ireland or the Colonel as Medical Director.

BROCHURE NO. 2

When did we first learn about this association? Brochure No. 2 was distributed. It was a bit of a supplement and a correction and re-edition of Brochure No. 1. We did not get the pretty picture in No. 2; but some one in one of the Government departments handed that to Dr. Verbyck, and he was on one of the committees of the District of Columbia Medical Society, and there was found outright a scheme under which not merely the employees of H. O. L. C., but all of the employees of all of the Government departments in the District of Columbia were to be grouped together under this plan.

It is needless for the prosecution to read any statement made by Dr. McGovern or Dr. Macatee or any of the others, because as men and women of Washington we know that when you take out of the District of Columbia practically all of the Government employees, then you have about half the population, when you take their dependents. But here, suddenly and unknown to the Medical Society, was this scheme which had been ripened to the point of fruition, so that already it had been carefully blueprinted and the way all set to go.

The District Medical Society was not concerned about that. It was concerned about one statement which, in substance, was this:

"After the plan is ready to launch, then let us try to get the cooperation of the District Medical Society."

In other words, wait until we are ready to go; wait until we are all prepared, and then let us spring it on the Medical Society. If they will come along—fine! If they won't, they are going to take it anyway.

Group Health did not cooperate. When the Medical Society read that in their brochure they sat down and wrote a letter to Group Health and said:

"We notice that you want to cooperate. Won't you come and tell us what the scheme is in which you desire cooperation?" So Mr. Penniman, Mr. Zimmerman, Dr. Brown, a very estimable old gentleman who had been in charge of hospitals under the Veterans Bureau in the United States Government and who had become persuaded by the allurements of this Group Health Association, until his mind was disabused and he resigned a year later when he found it could not work—they all appeared at the District Medical Society. Up to that time the District Medical Society had never met—and when I say "Society," I mean the responsible members of its committee—had never met a single human being connected with Group Health Association. They had never been invited by anyone connected with Group Health Association to learn what it was all about, what they expected to do or how they expected to do it.

That was sometime in June, and it followed the meeting which the prosecution called your attention to this morning, of June 1, 1937.

And now I ask you to stop with me just a moment in order that I may disabuse your minds of the theory upon which the prosecution proceeds with reference to dates antedating June 1.

You were advised in the opening statement of the prosecution that this conspiracy began on January 1, 1937, and existed down to the finding date of the indictment, which was December 20, 1938. Why they fasten on January 1, 1937, no one knows except the one who drafted the indictment.

The fact about the matter is that the District Medical Society never knew Group Health was in the convolutions of the brain of Mr. Rickard or Mr. Penniman on January 1, 1937. Therefore when Group Health Association had filed its charter on February 24, 1937, the District Medical Society was no more concerned with Group Health than you and I are concerned now with something we know nothing about.

But the prosecution was careful to call attention to a resolution which had been adopted by the District Medical Society, counsel says, within an exceedingly short time after the charter of the Group Health Association had been filed over here across the street in the office of the Recorder of Deeds; the inference being that the resolution was adopted because the charter had just been filed.

In order, therefore, to answer that imputation and inference and to show the positive lack of any basis in fact for drawing it, let me tell you this about this section. You will probably hear quite a bit about it. The prosecution read certain portions of it to you. It is that Section 5 and prescribes that the members of the District Medical Society should not have professional relations with those who were engaged in the practice of their profession under contracts which had not yet been approved by the District Medical Society.

That resolution had absolutely nothing to do with G. H. A. The first reason, and one wholly sufficient, is because the District Medical Society itself did not know anything about Group Health when it adopted that resolution. I think the prosecution was fair enough to state, and in so stating hoped that its statement would take your mind away from the purpose of the statement, that it was another clinic toward which that particular resolution was aimed. It was. They knew it was aimed at an entirely different clinic. They knew that G. H. A. had not been even organized yet. It was aimed at a clinic which was practicing medicine unethically and which the District Medical Society thought ought not to be permitted to operate against the public interest.

The District Medical Society did not act arbitrarily. It did not simply reach up to high heaven and grasp this mighty power which it possesses and smother this clinic. Before they moved in regard to that resolution they sought the advice of two of the most eminent members of the bar of this court, two Nestors of the profession, Mr. H. Winship Wheatley being one, and the other was one of the best known members of the bar who will come to testify; and I am going to keep him for a little surprise.

Those two lawyers went over the situation which confronted the practice of medicine in the District of Columbia from the standpoint of ethics and more particularly with reference to this particular clinic, and they advised the Medical Society of the District of Columbia that what they should do was to adopt a resolution which would be applicable to every kind of clinic which sought to set itself up contrary to the public interest and prey upon the public under the guise of practicing medicine.

That resolution was adopted then.

But to give this trumped-up conspiracy notion, that the District Medical Society passed that resolution against G. H. A., they point to the deposit of the charter on February 24, and they say that early in March we passed this resolution. I presume the sun should have stood still because Group Health was organized.

ORGANIZATION SECTION

JOUR. A. M. A.
FEB. 15, 1941

The second piece of evidence which I wish to draw to your attention and of which a great point was made by the prosecution. You will recall that a great deal was said about the tremendous power which the American Medical Association had gained unto itself, and also the District Medical Association in the District of Columbia, and it was this tyrannical abuse of this wonderful power which they had attained that crashed down upon G. H. A.; and they pointed out as one of the evidences of the misuse or abuse of that power the relationship between the hospitals and the American Medical Association and the District of Columbia Medical Association, and the use of that relation in the deprivation of the right to practice either on the regular staff or the courtesy staff of the hospitals in the District of Columbia.

While I am on that point, let me briefly explain to you just what the relationship of the American Medical Association and its constituent and component association is with reference to hospitals.

RELATIONSHIP OF A. M. A. TO COUNTY SOCIETIES

As the prosecution stated to you, medicine today is at the highest peak of excellence, of purity and of honesty that the world has ever known. One of the essential adjuncts of the practice of medicine, one of the necessary implements today, is the hospital. The hospital could not continue to exist without the doctor, and it is supremely difficult for the doctor to exist without the hospital. But each hospital is separately owned, independently managed by its lay group or lay board of directors.

Hospitals maintain two staffs, the general and the courtesy. The general staff is composed of those doctors who are elected to the position by the board of directors of each hospital. The general staff is subject to the call of the hospital, so that if at 12 o'clock tonight an accident occurs and some special treatment is required by someone who has been injured, the hospital calls a member of that staff who has special experience for the proper care of the injury which that patient has sustained, and that doctor goes, day or night. There is no 5 o'clock limit on him. Day or night he goes, and if that man cannot pay, he gets the service nevertheless without pay, because those men are on the staff, that general staff of the hospital, for that purpose.

On the courtesy staff we have those doctors who are permitted the courtesy of coming into that hospital to treat their patients. Therefore there is a unity of interest between the profession and the hospital in this: to keep the standards of the hospital to the very highest peak, and therefore the American Medical Association has watched carefully the hospitals of the United States. They have examined them. Why? Because of any economic reason? The prosecution cannot produce one iota of evidence that the American Medical Association in the inspection of a hospital ever had any economic purpose in mind whatsoever. We never heard about this "economic" matter until about 1932. The American Medical Association has built up the standard of care which the patient receives in the hospitals of the United States to the highest point in the history of the world. And how is it done? By inspection and seeing to it that the patient is properly cared for, that the intern is properly trained, that the resident has a proper opportunity to receive instruction under the tutelage and guidance of the members of the general staff. Those men teach the young intern today because they know that the young intern of today will be taking their places tomorrow; and the sole and only interest of these men who serve without pay on those staffs in instructing those interns and residents is to maintain the high standard of medicine.

And this testimony will speak for itself in resentment against the imputation that it was a dollar bill in the pocket or an economic competitive reason which impelled them.

Is not the general public of the United States interested to know just what the consensus of the opinion of all the doctors of the United States is with reference to a hospital?

The testimony, therefore, will be directed for your instruction to this point against the attacks made by the prosecution upon it—that the American Medical Association has given to a hospital which measures up to the standards which due and proper care in the public interest require a grade by stating publicly in its Journal that this hospital has received a grade which entitles it, first, to conduct itself as a hospital, and then to train the young men of today to be the doctors and surgeons of tomorrow; and the public can rely upon that standard.

That was not done in order to grasp or attain power. It was done in the whole-hearted, sincere, honest, sacrificing purpose upon the part of the medical profession to see to it that you and I, if we go to a hospital, shall receive the proper care which we deserve.

I had almost forgotten this. In 1935, long before even Mr. Penniman made the sudden and inspirational discovery that H. O. L. C. had some of its employees sometimes ill—and I believe the prosecution stated that Mr. Penniman discovered that because he was looking over the loans which had been made at the Credit Union, and the Twentieth Century Fund was interested in the Credit Union—away back of that there comes into the picture the Twentieth Century Fund and the Health Economics Association and the Good Will Fund.

But to return to 1935. At the meeting of the House of Delegates in Cleveland in that year the House of Delegates passed a resolution which was to the effect that they thought it in the public interest if the members of the staffs of hospitals throughout the country should be members of the American Medical Association.

That was not adopted by the House of Delegates except as a subject of the advice and consideration of the Council of the American Medical Association. In other words, the House of Delegates said, in substance, to the Council, "Here is what we were thinking about. Think it over; look into it. See what there is to it."

That was in 1935. Surely that could not have been adopted in 1935 with any view of G. H. A.

What was behind that? The purpose behind the resolution was this, that if the members of the staffs of hospitals belong to the American Medical Association, and if any member of any one of those staffs did not live up to the proper standards of their own conduct or in the practice of their profession, if they were not alert to see that proper care was used, then the hospital would have not only its own method to throw off the list such a person who was out of step, but the American Medical Association itself would say, "Here, as a member of our association, conform to these standards, or we will recommend to this hospital that you cannot belong to its staff."

It was a method which the American Medical Association had adopted in order to keep the standard of care where it should be.

Now, let us return to June 1st. That is where we were some minutes ago—the Group Health Association in its relations with the District Medical Society.

Brown, Penniman and Zimmerman came to the District Medical Society in response to the request which was made, and there they met the executive committee. The executive committee is composed in great part, and was then, of some of these defendants. I do not think it will be necessary for us to put on any reputation testimony for them. They have lived lives of honor. They have lived sacrificing lives, and they have won a high position in the community. Perhaps never before in the history of this country have you seen men of their prominence hailed before a court of justice as defendants.

Those men met, Drs. Brown, Zimmerman and Penniman; and they said "In this brochure you state you want our cooperation. Won't you tell us, please, what kind of a scheme this is?"

They had examined it, they looked over its structure, and they found that on paper the thing was economically unsound; that it was not going to be operated in accordance with the public interest.

So they asked "How are you going to operate this? You claim you are going to have a clinic, you claim you are going to have a medical staff, you claim you are going to give all these medical services to all these people in the District of Columbia. Under your set-up you take care of a hundred thousand people. It takes money to take care of a hundred thousand people. It takes money to get x-ray machines, to equip a clinic, to employ nurses. Where is the money coming from? We will cooperate if we know that the thing is economically sound, that it is ethically conducted, and in accordance with the public interest, but tell us something of your scheme." Is that unreasonable?

They were told "It is none of your business. It is none of your business where our money is coming from and we won't tell you."

And the meeting broke up.

Then, Dr. McGovern some time later wrote again to Mr. Penniman, I believe it was, and said, "Won't you give us a copy of your contract? Won't you give us a copy of your by-laws under which you lay down and prescribe the services you are going to render? Won't you tell us something about yourself, so that if you want us to cooperate we can do so intelligently?"

The distinction between the two groups in this case, the District Medical Society and Group Health is this: The District Medical Society never hesitated at any time to disclose every purpose and reason which motivated or actuated its conduct.

Penniman would not write, would not answer. He called on the telephone.

And Dr. McGovern met him down in the Raleigh Hotel, thinking the two of them were going to sit down as you and I would, sit down at the table and discuss it.

When he got there Penniman had a witness, Zimmerman, and he said, "Tell us where you are going to get your money. Tell us how you are going to operate this group."

He said "It is no more of your business to ask us how we are going to get our money than for you to go up there and ask Mr. Garfinckel what his agreement is with the express company."

Wasn't it?

Now, this is the cooperation which the prosecution told you this morning and yesterday this Group Health wanted from the Medical Society.

Now, at just about this time there was brought to your attention the white-list. Perhaps you heard the words. You have them now.

And they said that about this time the American Medical Society in further pursuance of this terrible conspiracy had gotten together in their committee meetings, they had formulated a white-list, they had circulated it to its members, and even circulated it to the hospitals.

Now, let me explain the white-list—or, once again, they complain because Group Health Association was not on the white list.

How could it be? They didn't open up for three months. They were not in existence. How could it be on the list?

And yet they draw that to your attention as part and parcel of this conspiracy.

Now, what was this white-list?

I tell you that that resolution section 5 was aimed at another clinic.

The prosecution named half of it, the Crawford's.

It was the Pennhallow-Crawford's Clinic.

That was declared to be operating not in the public interest, and therefore the District Medical Society had told its members this, and it is just and reasonable: "How can we permit a member of our Society to deal with a man who we say is not practicing medicine ethically or in accordance with the public interest? If we allow our members to deal with that man, then later on when the public finds out that this has been done not in accordance with the public interest, then they will say 'Why did you let your members join? What kind of an association are you?' You approved the association because you let your members deal with them."

So the Medical Association then said "Before anyone of us deals with anybody under a contract where he is selling his services under a particular contract, let us see what kind of a contract that is. See whether or not he can perform those services. See whether he actually is giving proper medical care. Or, is he just hoodwinking the public under the contract?"

"If the contract is sound we will approve it. If it isn't sound we won't approve it."

And there are eight or ten groups in the City of Washington practicing medicine in accordance with the ethics of the District Medical Society, and not one of them disapproved. Right now.

And every single group in the District of Columbia that was practicing under what they call contract practice on the date the white-list was formulated is on the white-list.

Now, why do they call it a white-list?

The District Medical Society sent it to its members and said "Each and every one of these clinics now operating in the District of Columbia is approved by us."

There were no others in the District of Columbia operating. The prosecution says "But they didn't put G. H. A.'s name on there."

Well, how could they when it didn't open until November 1st. And this was early in July.

Now, then, later in July after this meeting with Dr. McGovern when they could get no information whatsoever from this cooperative group who were cooperating so magnificently, they met again down in the headquarters of Group Health Association; the District Medical Society trying to cooperate.

They went down there again and said "Will you give us some information as to how you are going to operate?"

No. Won't tell you.

How could we cooperate when they wouldn't tell us how they were going to operate?

And every doctor in that group, every doctor in the Medical Association of the District of Columbia, and every doctor in the United States of America knew that if that group were going to operate under the plan which they put out at that time, which was in 1937, it required money.

Every one of them knew that these dues which they brought up could not support the group. And what they wanted to prevent was this:

The solicitation of government employees under the promise that they were going to get adequate medical care, when those who were doing the soliciting knew that they could not provide the adequate medical care because they didn't have the funds.

Now, just at that time, just along while this was brewing and the pot was boiling, as I am telling you about now, this group came to the president of the District Medical Society, Dr. Neill.

He sits over there as defendant now. He could have had the job of Medical Director. He didn't take it. There he is (indicating).

Dr. Neill said to Mr. Childress—and Mr. Childress was the right-hand man of John H. Fahey, and a very close friend of Dr. Neill, who had operated on his family—"There is a new group being organized down here in H. O. L. C., and would you like to take the job as Medical Director?"

And Dr. Neill's answer was this:

"You are the judge whether this is fair. If it is economically sound, if it is legal, and if it is ethical, it is the job I am looking for."

But he never could find out anything about it.

And so later on they got Dr. Brown.

Now, the point is this: In reply to what was stated by the prosecution, the District Medical Society didn't ask Group Health Association, Group Health Association kept its organization secret and confidential until it had become entirely and completely formed and ready for action.

And then it assumed a haughty, arrogant attitude that "We are going to put this thing across whether you like it or not," and they assaulted and attacked the District Medical Society, first, by taking its president, if they could get him; next, by taking their second one of its members, Dr. Lee, another one of its members.

And, if this thing is so good, why did they have to come into the American Medical Association which had been moving along since 1819 without trouble from anybody, and start in to disrupt its membership, when there are 69,000 doctors in the United States from which they could draw, and there were 1,200 in the District of Columbia from whom they could draw.

The point is, and the testimony will show, that just as General Ireland stated, it was an entering wedge with the stage, as Mr. Kelleher has said this morning, national in scope, to destroy, disrupt, confuse, and then rebuild the practice of medicine, according to the ideas of these theorists.

I believe I was just discussing with you before the short recess the meeting which has been held at the headquarters of Group Health in connection with the projected cooperation between the two organizations to procure the end and purpose of what Group Health desires.

Suffice it to say that the conclusion of that meeting was simply this:

The refusal on the part of Group Health to disclose anything of its financial capacity or ability to function, and the statement by one member of the board of trustees for Group Health that it was very evident that the two could not get along, and they were going along, meaning Group Health, at all events, and if the District Medical Society desired to withhold its judgment with reference to what Group Health was doing, kindly do so until the District Medical Society saw what Group Health could do.

That was in the summer of 1937.

And at that time, with the knowledge on the part of any doctor, whether he were a member of the District Medical Society or not, that no organization like Group Health could possibly proceed to success without some financing of some character sufficient to warrant the character and type of service indicated in the brochure, the District Medical Society from then on had but one intention, and one purpose, in view, to see what the operation of Group Health was with respect to its functioning in the public interest.

Group Health refused to submit its contract to the Medical Society.

It demanded its cooperation without giving to the Medical Society any information whatsoever.

Then, subsequently, the reason for the refusal became apparent.

THE \$40,000 APPROPRIATION

The representations which I spoke to you about earlier, which Mr. Penniman gave to the board of H. O. L. C. with reference to the cost to that organization growing out of sick leave taken by its employees was made the basis for the appropriation from public monies of \$40,000.

I think that sum was mentioned or described as the paltry sum of \$40,000, by the prosecution; to guarantee the beginning only of Group Health Association.

In order to conceal the purpose of the misappropriation, Group Health in March had entered into a contract with H. O. L. C. under which it agreed to give medical and hospital services to the employees of H. O. L. C. for a period of two years, for \$20,000 a year.

Then, Group Health found itself in a financial situation where it couldn't finance the equipment for the clinic, just as Dr. McGovern had in his mind when he asked the question, "Where are you getting this money?"

And instead of paying this amount of money over two years in accordance with the contract, within six months every dollar of it had been paid to Group Health, in order to equip its clinic.

John H. Fahey, who was then a high officer in Health Economics Association, who was still a higher officer in the Twentieth Century Fund, was chairman of the board.

But never would Group Health Association disclose the fact that this misappropriation of public funds had been made in order to guarantee merely its beginning.

One step further, they utilized the facilities of Home Owners Loan Corporation to purchase equipment at government prices, a privilege which no organization has the right to exercise except the Government, and bought practically at cost the equipment which went into H. O. L. C.

Lawyers of H. O. L. C. were utilized to carefully instruct, formulate and supervise the structure and conduct of Group Health Association.

I say this in reply to the statement made by the prosecution that we might say that Group Health Association was connected with the Government in some way, but that in fact Group Health was an independent corporation entirely distinct from any governmental activity.

Why, the trustees of the Twentieth Century Fund had on their board four of the highest government officials we have today when this \$40,000 misappropriation went through.

John H. Fahey, was chairman of the board of H. O. L. C. The Solicitor General of the United States was on the board of the Twentieth Century Fund.

The Attorney General of the United States was on the board of the Twentieth Century Fund.

And one of the highest state officials was on the board of the Twentieth Century Fund.

We say that for you to judge whether this was a government attempt to destroy the Medical Society of the District of Columbia and the practice of medicine as it had been known for over a hundred years.

Now, then, that misappropriation came under the watchful eye of Congress, and also the Comptroller General of the United States, and, you will recall, counsel for the prosecution justified or attempted to, that \$40,000 transaction by saying that the Home Owners Loan Corporation was authorized to determine the character of its expenditures, regardless of any other law of the United States, and therefore, since that provision was contained within either an appropriation act or some other act of Congress, it had the right to take \$40,000 and start a grocery store or a meat market if it so chose.

When the chief counsel for H. O. L. C. was before the subcommittee of appropriations of the House on the 18th day of December, 1938, and Mr. Woodrum asked him the question:

"On what justification did you take these \$40,000?" He made the same answer counsel for the prosecution made to you, and Mr. Woodrum said "That is the first time since I have sat on the Committee of Appropriations in any Congress of the United States that I have heard a public official ever advance that sort of a reason for the misappropriation." And then added "It is the unanimous opinion of this committee the appropriation is illegal, and, hereafter, it shall not occur unless specifically authorized."

And when the matter was brought before the Comptroller General of the United States he answered the contention as made by counsel for the prosecution and supplied to Senator McKellar—or, perhaps it was to Pat McCarran—I believe it was,—he enclosed the documents which backed up the statement as made by the prosecution, and the Comptroller General said that from everything he had reviewed—and he had everything that was then in existence—that misappropriation was entirely illegal and contrary to the laws of the United States.

Now, counsel for the prosecution said this morning to you in his statement that he was going to prove to you that doctors don't care about the violation of the laws of the United States, they were just making this opposition on pure competitive reasons.

How much then from this testimony does it show G. H. A. cared about the law of the United States?

It was precisely, as the testimony will show, a determination to put this over legally or illegally.

Why do I say that?

In the 1936 annual report of the Twentieth Century Foundation or Fund, you heard about Rockefeller Foundation, and you have heard of another foundation this morning, but this is called fund.

They gave a report of what their activities in establishing groups and prepayment plans throughout the United States had been. And they made this significant statement in that report:

"In substance, we cannot establish this group practice in many of the states because it is forbidden by law, and therefore we have applied to the legislative bureau of Columbia University to find how we can get around the law."

And when Group Health first started it put out early in 1937 a series of by-laws or regulations, and as late as November 6, 1937, when the general counsel of Group Health Association was submitting to the board of the H. O. L. C., amendments to those by-laws for the approval of that board, he said the reason he was making the amendment was to improve the legal position of the Association. And that if they should be held to be an insurance company, then he thought the legal position of the company—of the association, was strengthened by this amendment.

That was in November 1937.

Now, much water had gone over the dam since they had refused to disclose to the District Medical Society anything at all about themselves, since they had refused to tell about the \$40,000, and at that time a fact which we for the defense were astounded and astonished the prosecution did not bring to your attention, the two chief prosecuting officers who represent the enforcement of the law in the District of Columbia, were investigating the legality of Group Health Association.

And at that time, in November, the District Medical Society had employed counsel to give them advice as to whether Group Health Association was legally doing business or not.

This we offer on the question as to whether the Medical Association of the District of Columbia was regardful of the laws of the United States and their own conduct with respect thereto, throughout this entire controversy.

At that time, therefore, when Group Health knew that its conduct was under the investigation of the Corporation Counsel of the District of Columbia, and the United States Attorney of the District of Columbia, whose office is right here in this building, it commenced a course of conduct which it never finished until May 2, 1938, and this is what counsel for the prosecution did not disclose to you.

Just as the Medical Society of the District had employed counsel to advise them with reference to Section 5, they employed counsel with reference to the general legal structure and method of doing business of G. H. A., in order that they might be advised as to whether they could cooperate, as to whether it was a legal institution or not, or as one which they had a right to protect themselves against assault made by it.

The reason why they employed counsel grew out of a conference which was had on the 2d day of November, 1937, in the city of Chicago.

At that time the District Medical Society sought the advice of older and wiser and more experienced heads and those who were in information nationally with reference to the practice of medicine in this country.

They went to Chicago and asked these terrible men, Dr. Woodward—I don't guess there is anyone on the jury old enough perhaps to remember when he was in charge of the Public Health Service of our own District of Columbia, but I had the honor of sitting under him when I was taking my law and post-graduate in Georgetown. He was then here in the District of Columbia. This man now sitting as the defendant. They asked Dr. West what he would do in this situation in the District of Columbia.

The sum total of that advice by these conspirators was "Go back home and employ legal counsel who can make an investigation of the organization and see what it is all about."

They came back home.

Counsel advised them that the Group Health Association was practicing medicine in violation of the healing and practice act in the District of Columbia.

Counsel also advised them that it was conducting an insurance plan without having obtained a license from the Insurance Commissioner of the District of Columbia.

With that advice the District Medical Society then presented briefs of counsel to the Corporation Counsel in the District of Columbia and to the United States Attorney.

And in December of that year the United States Attorney for the District of Columbia told Group Health that if it didn't stop doing business, he would stop it, that it was violating the law.

And the Insurance Commissioner of the District of Columbia told them that if they didn't stop, that he would stop them, and that they should take out a license as an insurance company.

That was in December.

Counsel then this morning pointed your attention to the exemplary conduct of Group Health Association, by coming into this court of its own free will and petitioning this court for advice as to its legal status.

Group Health Association, as this testimony will show, never came into this court until the United States Attorney and the Corporation Counsel drove it in.

And then they came in here on January 15th, and they set up under the corporate oath that the United States Attorney and the Insurance Commissioner of the District of Columbia had threatened to close them up and they wanted this Court to determine whether they could continue to do business or not.

And then the prosecution tells you this morning that Justice Bailey in the latter part of July, on the 27th, declared they were legally in business, and he gave his blessing to the transaction; and he never told you what happened.

Just as soon as they filed their petition in January, Group Health commenced new amendments.

They amended their charter again, that month; then they amended their by-laws again, on the second day of May, right while this petition was right in this courthouse, just before it was argued in June.

They took every single objection which counsel had placed before the United States Attorney and the Insurance Commissioner of the United States, and they changed their by-laws to meet those objections.

So that the Group Health which Justice Bailey determined was legally operating was no more like the Group Health which had been fighting the District Medical Society than the wolf is like Red Riding Hood.

That is the organization Justice Bailey passed upon.

And then, within four days, Thurman Arnold announced: "Now, we are going to indict every last one of you."

No opportunity given then for the District Medical Society to determine its attitude; showing that from the beginning—and I will bring you a few more instances which, the testimony will show, that this is not an arbitrary statement or a reckless one made,—from the very beginning Group Health was determined to go forward with this experiment against any opposition, by any means legal or illegal, and that it had behind it the prosecuting office of the Attorney General who was going to add its authority.

Thurman Arnold did, in this case, by public announcement within four days after Justice Bailey's decision.

The Corporation Counsel took up the question of the practice of insurance to the Court of Appeals.

Did Mr. Arnold take this end of it up? Oh, no.

The Court of Appeals has declared whether or not G. H. A. is now legally practicing is an open question in the District of Columbia.

Now, then, I told you that from the beginning Group Health was building evidence so that it might through the prosecuting officer stand before you and make just the statements that were made.

I told you that when Dr. McGovern way back in July met Mr. Penniman for what he thought to be a friendly chat over the luncheon table in the Raleigh Hotel, Mr. Penniman took a witness along.

When they went down the following month to the headquarters of Group Health Association to have their conference there were stenographers there taking everything down stenographically.

And then when you hear these incidents which are brought to your mind, I want you to get all the facts about it, so that when the testimony comes along you will understand.

You will recall that the prosecution stated that the means by which we proceeded to attack Group Health Association fell into three categories, and he classified them first, with reference to attacks made upon Group Health in order to prevent its getting doctors on its staff, or, if it got doctors on its staff, retaining them thereon; secondly, with reference to the right of a doctor to consult; and third, with reference to the hospitalization of patients of Group Health.

Now, let this be understood now, the District Medical Society never objected to a patient of Group Health being treated in

any hospital in the District of Columbia at any time for any disease or purpose.

The hospital objected only under certain circumstances, which I will detail to you in just a moment.

Group Health insisted not that the patient be entered in the hospital, but that its doctor also treat that patient in the hospital.

THE CASE OF THE TECHNICIAN WITH HEMORRHAGE

Now, you will recall that one instance which was brought to your attention was with reference to a young lady who was described to you as a technician within the clinic of Group Health Association, and who suffered a severe internal hemorrhage, and she fell swooning on the floor; and I thought that perhaps she would die before he got through telling us about it.

And then, the surgeon wasn't permitted to operate until he went through a long series of questions and investigation about his right to operate on her.

And you will recall, coming as a surprise, I asked if that was Miss Tew, and he said no, that was Miss Stuart. He was coming to Miss Tew later.

Miss Stuart never had an internal hemorrhage any more than you or I had.

She went to Garfield Hospital; she was operated on at Garfield Hospital by Dr. Schoenfeld.

She arrived in Garfield Hospital about ten o'clock. Her room had been assigned; she was prepared for the operation; she was operated on at 12 o'clock. There was no internal hemorrhage and if that is denied and she waives the privilege Dr. Schoenfeld will come in here and tell you that. The next instance was Miss Tew, and this we offer for the purpose of bringing to your attention the attitude of Group Health Association.

Just as I told you earlier, Group Health Association never sought the advice of a single doctor of the District Medical Society with reference to its formation, the character of its services, the cost of its services, whether it could be rendered or not for the benefit of the patient. Neither did it ever seek or make request of a single hospital for admission to privilege of a single doctor of H. O. L. C. until as the prosecutor said, "After we were ready to be launched."

They knew just as well as you and I do that the lights are burning here in the ceiling that before any doctor in this District of Columbia or any place else has the right to go into a hospital in order to treat a patient he must get the permission of the hospital; that is a reasonable provision, for this reason: No hospital could, in the public interest, or in the patient's interest, conduct itself by permitting every sort of a doctor,—one who has violated every standard of good practice—to come into its hospital. It could not possibly exist without the protective regulation known to every hospital throughout the United States, and I don't think I am exaggerating when I say the word; that a doctor is privileged but he has no right to practice. That question has been determined by this Court. He has that privilege; he has no right to it.

Then Dr. Selders, of whom you have heard quite a bit, didn't ask for the privilege; not a single member of the staff asked for the privilege, but this chap Penniman, the supervisor of personnel, a layman with no more knowledge of medicine than any one of us has here; Penniman, a layman, arrogantly rushed to the hospital and told them he wanted the privilege for his entire staff.

Now, it is customary for hospitals to make investigations into the character and the experience and ability of doctors who make application to practice in hospitals—a reasonable thing. The doctors made a reasonable investigation, or, rather the hospital made an investigation into Dr. Selders and, just again to show you how information is given to you, the prosecution says, "There was a man 45 years of age," and I know you thought—because I could see it in your eyes—there is a man who has been practicing his profession for 15 or 20 years—and the hospital denied him privileges.

The ink wasn't dry on the right of Dr. Selders to practice surgery when he joined the G. H. A. He just had come out of the Worcester General Hospital at Worcester, Massachusetts. All the operating he had ever done was under the supervision and direction of the staff of the Worcester Hospital; and he came down here and made an application to the hospitals of Washington to perform every kind of an operation except brain surgery. And, "We say the man should have been accorded that right because it is G. H. A.; and being employed by G. H. A. he had the right to do just that. We can take \$40,000 of public moneys; we can use it anyway we want; we can violate the law if we want to, because we are G. H. A."

Those doctors gave him a very careful examination, as they do every doctor, and they didn't think a man who had just come out as an intern of a hospital should have the right to

practice surgery of all kinds in the City of Washington, in its District hospitals.

Now I hope they won't try to tell us more about Dr. Selders. He resigned in 1938 from G. H. A.; Dr. Brown resigned just before that. I am not going into that at least at this time.

Now, then Dr. Selders, when this blank application was made by Penniman, had been given the customary privileges by the Garfield Hospital which were allowed to any doctor upon the assumption that having been licensed to practice in the District of Columbia, pending this period of investigation he could have certain limited privileges; those which did not involve operations so serious as to endanger human life. Those privileges expired. Dr. Selders knew they had expired; Columbia Hospital wrote him a letter and told him that the privileges had expired under the terms of the original grant, and that pending the determination of the legality of Group Health Association by this Court they said they should not extend privileges to him. In other words, at that time, in February 1938, Group Health in the judgment of the District Attorney and Corporation Counsel was operating contrary to law, and pending the determination of whether Group Health was operating in accordance with law, Columbia made that straightforward statement to Dr. Selders. In less than three weeks Dr. Selders had the presumption, the arrogance, with the full knowledge that he had no right to try surgery in the Garfield Hospital, to send a patient up there and said, "I am going to operate on her." Did that young lady go as any other young lady would to the hospital? No, two witnesses with her; a man, a member of G. H. A., and a lady, also from G. H. A. She was not taken out under the influence of morphine. This is what happened: She came in to the hospital; she was assigned to her room; the nurse started to get her ready for the operation. The doctor came in and upon inquiry he learned it was Dr. Selders who was going to operate. "Why," he said, "Dr. Selders, you know, has no privileges in this hospital. We have our entire staff." Selders knew that. Selders knew he had no right to come in there. And then she, together with her two witnesses, said, "No," making evidence so she could testify. She didn't have an acute appendicitis case. Selders said she had because all hospitals permitted doctors to operate in an emergency. Now, if Selders could make out she had appendicitis he could operate. So she got up and dressed and went out. She had the nurse in attendance in preparation for the operation, and the nurse administered to her some kind of a sedative. She got out to the taxicab, left, and got another doctor who operated on her in Columbia Hospital; an ordinary appendicitis case—no hemorrhage whatsoever. She could not take another doctor at Garfield because she had these two witnesses, and then the prosecution could not make that representation that she did. Now then, let us just say this in answer to the three categories in which the attack, so-called, has been classified by the prosecution. Let us take the question as to whether or not the District Medical Society made an unjustifiable attack upon Group Health Association to prevent their obtaining doctors on their staff. The answer is No. 1. In the District of Columbia alone there were 1,200 doctors, any one of whom they could have drawn. The second answer is this: As I told you, the District Medical Society is purely voluntary. You can join it or not, just as you please, provided you have the qualifications of a doctor. Now, when you join it, one of the conditions is that you live up to the rules and regulations of the Society which you have joined. If you join the Masons you have to live up to the Masons; if you join the Knights of Columbus you must live up to the Knights of Columbus; if you join the Elks you must live up to the Elks; you cannot violate its rules and expect to remain a member. A man cannot parade as a member of the Masonic order and violate all its rules and regulations. Scandiffio knew when he joined the Society of its rules and regulations. He ought to. They have been the same since 1819, almost. The American Medical Association ethics have been such since 1847, and Scandiffio knew he had no right to join G. H. A. until he first had his contract with G. H. A. approved, and so did Dr. Lee, because both Dr. Scandiffio and Dr. Lee were aware of the regulations.

Then what happened? Then the legal staff of Home Owners' Loan took the case in hand. Here was a chance to make more evidence, so they promptly advised Dr. Scandiffio to withdraw his resignation and make the District Society prefer charges against him, and that is precisely what Dr. Scandiffio did; and when Dr. Scandiffio came up to answer the charges he had a battery of lawyers, five of the high counsel of Home Owners' Loan Corporation, and they are the ones who built up this record he said he wanted to introduce for you to read.

If you have time to read it, if we don't all celebrate the Fourth of July sitting here, I want you to read the haughty arrogance of those five men who demanded the right for Scan-

diffio to be on their staff, and at the same time to remain a member of the association, whose rules and regulations he violated. That is to say, nothing should be done against Group Health. They talk of persuasion, and I am coming to that; yet when we use persuasion they condemn it as an act of conspiracy.

In other words, Group Health could employ whomsoever it wanted in violation of the rules of any organization, and if the organization said you have your choice: you can still be a member of the Medical Society but you cannot be on Group Health's staff too, he said "I will be both"; that is Scandiffio. And don't forget, at the time Scandiffio was being tried because he had taken employment from an organization which had refused to furnish any information whatsoever to the District of Columbia Medical Society, and concerning which the Medical Society could learn about only from what it could pick up here and there; at the very time Scandiffio was being tried it was the considered judgment of the two chief prosecuting officials of the District of Columbia that Group Health was violating the law; and yet it is an act of conspiracy, and in furtherance of a combination to violate the Sherman Act, because the District Medical Society refused to have it said of it that it would have a member on its staff which was operating or assisting in operating in an organization that was violating the law. That is Scandiffio.

Lee presented his resignation at the same time Scandiffio did but he didn't go so far as to follow the advice of counsel of H. O. L. C. and make a battle out of what ordinarily would be gentlemanly conduct, to wit, "If you don't like to remain with the organization, resign."

Now then, we get to the second phase, that is, the consultation. That goes back one time more to this section 5, which I spoke to you about.

You know it is difficult, quite, to comprehend the psychology of the prosecution in the presentation of its facts; what it is going to prove. They have told you in one breath that this Group Health Association was an experiment which would give adequate medical care at a cheaper price. Now don't forget, the only thing involved in this case is price, price, price. These men are engaged in an economic experiment. If they would only leave the practice of medicine alone there wouldn't be any difficulty, but in the assumption of the right not merely to make an economic experiment, but also the right to control medicine, they have clashed with an organization which over the centuries has learned how medicine ought to be practiced in the public interest, and it is the only group on earth who can determine that. Now, they say that this organization was equipped to render this service. If so, why did they need to consult with other doctors, members of the District Medical Society? They had 1,200 other doctors in the District to pick from. Why is the point of attack aimed at the District Medical Society? Because evidence is wanted. In other words, if they might collect enough of these circumstances here to present in a proposed speech as to what they are going to prove they can make it appear to you that the District of Columbia Medical Society was out to destroy Group Health Association, and the District Medical Society, representing 825 of 2,000 doctors, was going to do that. The fact of the matter is they were out to destroy the District Medical Society by this new experiment which if it succeeded as intended would do. In other words, if you take everybody who needs medicine away from the doctor, the doctor has got to stop his practice of medicine.

Now, the interesting question is going to arise, where is the patient going to go whom Group Health doesn't take care of? The result will be that the District Medical Society and all medical societies in the United States, having been destroyed in the confusion which results,—the opposition which they fear will no longer exist,—and then they can superimpose on the practice of medicine as it has been known this practice in accordance with their theory.

Now then, the theory of what was done with the hospitals is so closely related to what Group Health offers its members that let me very briefly go into this because I see my time is slipping; I know you must be very tired of listening to lawyers harangue.

I think you have heard it said so much by the prosecution about this being a consumer cooperative whereby those in the low income bracket were able by budgeting medical expenses to protect themselves against a cataclysm which might bankrupt them or so destroy the family finances that they would no longer economically go on.

Now let us see what Group Health is. You would think, would you not, that the association or group which has been pictured by the prosecution to you would be a group who needed medical care. That clinic was organized and equipped to function for those who need care, you would suppose. It was not. Before you go into Group Health you must pass a physical

examination. If you don't pass the physical, you don't get into Group Health. In other words, if you have some ailment; if you are a sick man, what becomes of this claim of medical care; you cannot get it.

Now suppose you happen to slip by the doctors' examination and sometime within the next thirty days or within three years you develop a disease that requires more than one treatment within two years. You need it; but if you get it you pay for it. In other words, the very ones who need the care don't get it. Who is going to take care of them? Dr. Brown answered that in the conference of June, 1937, up in the office of the Medical Society in the District of Columbia. They said, "What becomes of them?" "Oh," he said, "we will give those to you." Kind of him, wasn't it?

Now, number 1: I suppose the answer to that will be, "Oh, this is preventive as well as curative." Whether it is preventive or curative, nobody gets in unless he passes this examination.

THE LOW INCOME BRACKETS

Now, about the low income brackets, and I think you are going to hear a lot about someone in Arkansas and Missouri and Texas not getting proper care. Let me impress upon you one thing: this conspiracy involves the Medical Society of the District of Columbia only, and don't let your minds go wandering off down there to Arkansas and Texas; don't get confused about this background. The District of Columbia has never been wanting for doctors. There is a doctor for every three to four hundred people in the District; the Group had only a doctor for one in every eight or nine hundred. So all this talk about what happens in Arkansas, Missouri and Texas, whether it occurred in the wilds of the woolly West had nothing to do with the District of Columbia.

Is it for the low income people? Not at all. It is for anybody. Some of their high officials belonged to Group Health. The man who is able to pay for medical services got the same service as the poor charwoman who would have gotten it from any doctor in the District for nothing.

It isn't for the man who couldn't afford medicine because if you don't pay your dues within ten days you are out; that is within ten days after the first of the month. So at the very time you need the Group Health experiment most is the time you don't get it.

What becomes of the man who can't pay his dues? He falls back on the defendants; they take care of him. The thing was commercialized from the very outset. It was so very extensively commercialized that standing up against that little clause I quoted from the charter of the corporation of the Medical Society of the District of Columbia, which said that under no circumstances can this corporation control the prices at which services shall be rendered; and standing against the very first section of the constitution of the A. M. A. which said that the practice of medicine shall be for the good of humanity, the distinction is so obvious. They not only require the payment of dues but they—when they first started and until they found that was illegal too—they put on a check-off system, the system that labor unions use in the factories and mines, and the boss deducted from the employees' checks the amount of his dues; and they still retain in their by-laws after they have amended them so many times that the by-laws today resemble in no way the by-laws under which they began, they still say that in the event of dissolution of Group Health and the sale of its assets, equipment et cetera, everything which it may own, that the corporation shall have a first lien on any dividend which any member might get.

Now, what is the type of service which they render? They render the ordinary clinical services just as they said Dr. McGovern had made a report upon to the Medical Society after it was found that they could not render the services which they proposed to render at anything like what it cost to render such services. You had heard this morning that the cost of medicine had risen with the cost of equipment such as x-rays, and that is precisely what took place. They were compelled to do two things: first, cut down the service and then raise the price so that the character or type of services, and the cost of it today are in no wise what they were when they began, but the peculiar objection which is offered in reply to the argument of the prosecution to it that the staff of G. H. A., unhampered, unrestrained, and uninterfered with determined the type of medical care of the patient,—that is the point which they raised as you will recall—no longer exists, and never did, except in Group Health.

Dr. Brown was compelled to resign because having believed from a reading of the brochure of the conditions there described, and believing that if there was any way, shape or form whereby they could be remedied that he ought to try it, he did accept the position as Medical Director. He then found that his

efforts as a director were being thwarted and hindered by the board of trustees. Who is the board of trustees? Once again on the question of whether it is a government institution or not. H. O. L. C. has two men on the board. The amendment and by-laws must all be approved by the H. O. L. C. These trustees are laymen. The constitution and by-laws provide that on 15 days' notice they can change the character of service which is being rendered. In other words it violates that clause of the code of ethics of the medical profession which says that between the doctor and the patient there shall be no third person intervening.

Because the doctor alone knows how to care for the patient, and some layman should not come in and try to tell the doctor what should or should not be done.

Then again, for the same reason, it destroys the relationship which exists, the confidence between the patient and the member; but the answer to the prosecution of that this morning was that they preserved the freedom of choice because the member could go and employ another physician if he did not like the member of the staff of G. H. A.

Well, if they destroy this fee for service basis, which they discussed, and they destroy those who were practicing medicine, what becomes of those whom the G. H. A. can't or won't take care of?

I am not going to exhaust your patience or your time or wear you out with an analysis of G. H. A. Their by-laws, together with their amendments and the practices pursued by this Association to avoid the inevitable judgment that it was an illegal institution and illegally conducted business and the fact that it was an insurance company which was doing an insurance business without a license, will all be presented to you for your consideration and you will see how skilfully guided the G. H. A. was with the backing of the Health Economics and the good will to avoid a decision and determination which they expected to be true when they filed the amendments here in order to obtain Judge Bailey's decision.

I think the prosecution said to you that the Twentieth Century Fund, the Health Economics and the Good Will Fund had nothing to do with Group Health. I think the evidence already directed to your attention indicates the contrary; but you will find from the annual reports of the Twentieth Century Fund where the monies are, of thousands of dollars being donated to Group Health so that for a time Group Health was able to operate upon subsidized funds; and the Good Will Fund or the Health Economics Association sent down here a person who from August, 1938, had been taken from the Rural Electrification Association, and installed in offices at 1422 I or K Street, paid for by one of these funds, and his salary paid for by one of these funds for the ensuing year.

Yet, the very purpose for which Group Health was formed was what? Mark you, I am merely following the language of the prosecution: to supply to the employees of H. O. L. C. this adequate medical care at reduced cost, and when Group Health started out, it starts out with employees of H. O. L. C. in its membership, some 2,000, and then had 200. They have now gone out and tapped other Government departments to keep up this membership in it, and instead of giving these medical services to H. O. L. C., and under that representation they got the money, \$40,000, they are now doing practically nothing for the employees of H. O. L. C. and never took over the emergency rooms in H. O. L. C. They are obtaining new memberships from new ones whom they have gone after by solicitation and by advertising through their names.

HOSPITALIZATION

Now, I am going to comment briefly on the hospitals in the District of Columbia. Throughout this case you will find nothing which the American Medical Association, as an association, has done as a conspirator in this case. You will find nothing which the Harris County Medical Association has done, or any other association, including the Medical Association of the District of Columbia.

Counsel for the prosecution concedes to us the right of honest, fair persuasion; at least they give us the right to disagree.

We disagreed with Group Health on good grounds and for good reasons, and since the decision in Judge Bailey's instance there has not been any hospital committee in the Medical Association of the District of Columbia.

The only instance in which the hospitals have been approached at all was first by a letter of July 29, 1937. That was the letter in which the "white list," so-called, was sent to the hospitals, and not a member of the District Medical Society ever knew that list went to the hospitals because there was no authorization to send it to the hospitals; the authorization was merely to send it to the members of the Association itself.

But whether it was authorized or unauthorized there could have been nothing in the "white list" itself to complain about because of the absence of Group Health's name thereon because Group Health had not been yet organized.

Then we come to the resolution which was read to you verbatim by the prosecution sponsored by Dr. Willson.

That resolution was offered in a Society meeting, and the prosecution knows and knew when they represented it to you that that resolution was referred to a committee, and the only action taken on it was "Pass it on to a committee and let us see what it is all about."

Then what was the result of that resolution? There came out of that committee not the resolution which was read to you this morning but the resolution under date of December 1st, 1937, which was sent to the hospitals on the second day of December, 1937, and that resolution so stated squarely "For educational purposes alone, we brought your attention to the recommendation that the members of the staffs of hospitals be members of the American Medical Association." That was the resolution.

Now, they impugn that resolution, saying to you that it does not mean what these honorable gentlemen said when they wrote it, but behind it is some infamous purpose which never originated in the mind of anyone except for purposes of prosecution.

With reference to the hospitals in the District of Columbia and the American Medical Association letter or response thereto, which was called to your attention this morning, occurring in August, 1937, and more particularly, I think from either Columbia or Georgetown, may I say this: there again in August, 1937, Group Health had not even started to function.

But, the point of the prosecution seems to be that once somebody had the thought started, then everybody else must bow down and do nothing about it. He could not even use persuasion, which is given to anybody under the Constitution to use, but everybody must bow down before the G. H. A.

Now, it may surprise the prosecution to know that Dr. Cutter of the American Medical Association who wrote the letter never had heard of Group Health Association in his life when he wrote it.

That was one of the ordinary, orderly routines of investigation which was made by the American Medical Association and

which has been made year in and year out over an extended period of time, and it was at that time suggested to the Washington hospitals that if they could they should have on their staff members of the American Medical Association, just as Group Health here tried to get members of its staff on the staffs of hospitals, but the right which we tried to exercise is urged upon you as an act of conspiracy, a pressure, a tyranny, and a destruction.

Therefore what becomes of the point that any attack was made upon Group Health, in so far as the hospitals are concerned, when we consider that at that time under the studied and deliberate judgment of everyone who had looked over Group Health itself, it was operating contrary to law and was an illegal institution, and they can't point to a thing following that declaration. I think he told you eight hospitals have members of Group Health upon their staffs since the declaration by Justice Bailey.

You will see from the testimony that Group Health, the Group Health of 1938, was an entirely different institution from 1937.

Now, then, I think, ladies and gentlemen, I won't take up any more of your time and I won't talk any further, but these briefly are the headings and the outlines of what this testimony will show, probably extending over quite a time because of evidence which is documentary, but you will find furthermore that every explanation which is made is supported, in so far as the District Medical Society is concerned, by its own documentary proof.

They have objected to the theory of it. Yes. That they will testify in their objection. Yes.

Up to that point they expressed that objection in a way in which they were motivated and actuated only and solely for the benefit of the profession. In the practice of medicine where any assault was made upon them they were compelled to meet it because they knew the head and the front of the institution directing that assault was doing so for the purpose of destroying it in order that the experiment, the future of which they confessed themselves this morning, they knew not about whether it was good or bad, they could not tell you, but let the experiment go on, and then some time later there will be confusion and destruction.

(To be continued)

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—H. R. 2112 has been reported to the House, without amendment, proposing to authorize the Secretary of the Navy to appoint in time of war or national emergency declared by the President to exist, for temporary service, such acting assistant surgeons as the exigencies of the service may require. H. R. 2278 has been reported to the House, without amendment, proposing to authorize the Secretary of War to detail not to exceed 2 per cent of the enlisted men of the regular army as students at such technical, professional and other educational institutions, or as students, observers or investigators at such industrial plants, hospitals and other places as shall be best suited to enable such enlisted men to acquire a knowledge of or experience in the specialties in which it is deemed necessary that such enlisted men shall perfect themselves.

Bills Introduced.—S. 666, introduced by Senator Walsh, Massachusetts, proposes to establish in the Department of Labor a Bureau for the Welfare of the Deaf to (a) collect, tabulate and make public statistics pertaining to the deaf, their employment and their welfare; (b) ascertain what fields of employment are available to the deaf, and to endeavor to create new such fields of employment; (c) acquaint employers in private industry with the special capabilities of the deaf and to encourage the employment of the deaf on an equal basis with the hearing; (d) cooperate with the heads of the various departments of the government and with the Civil Service Commission and states and political subdivisions thereof in expanding the opportunity for the employment of the deaf in public service, and (e) cooperate with any public or private agency in the vocational rehabilitation of the deaf. S. 697, introduced by Senator Clark, Missouri, proposes to amend the section of the Selective Training and Service Act of 1940 relating to the deferment of college students so as to provide that any person who, during the year 1940, entered on attendance for the academic year 1940-1941 (1) at any college

or university which grants a degree in arts or science to pursue a course of instruction satisfactory completion of which is prescribed by such college or university as a prerequisite to either of such degrees; or (2) at any such university to pursue a course of instruction to the pursuit of which a degree in arts or science is prescribed by such university as a prerequisite shall, while pursuing such course of instruction at such college or university, be deferred from induction under the act (a) until the end of such academic year, or until July 1, 1941, whichever occurs first, if he is ineligible, under the established rules and regulations of such college or university, to complete such course of instruction before Feb. 10, 1942, or (b) until he completes such course of instruction, or until Feb. 10, 1942, whichever occurs first, if he is eligible, under the rules and regulations of such college or university, to complete such course of instruction before Feb. 10, 1942. H. R. 2099, introduced by Representative Tolan, California, proposes to amend the Social Security Act so as to provide grants to the states for needy disabled adults incapable of self support. H. R. 2817, introduced by Representative Knutson, Minnesota, proposes to exempt from the taxes imposed by the Social Security Act service performed in the employ of a voluntary employees' beneficiary association providing for the payment of life, sick, accident or other benefits or the furnishing of medical care or hospitalization, to members of such association or their dependents, if no part of its net earnings inures to the benefit of any private shareholder or individual, other than through such payments and if 75 per cent or more of the income consists of amounts collected from members and/or contributed by the employer for the sole purpose of making such payments and meeting expenses. H. R. 2858, introduced by Representative Allen, Louisiana, provides that where, as a result of sound medical evidence and/or examination, it has been established by the United States Veterans' Administration that a veteran's service-connected disability, resulting from his service in the armed forces of the United States during any war, has

caused a severe industrial inadaptability, then in that case the veteran shall be considered as permanently and totally disabled and shall receive a rating of permanent and total for compensation purposes and for any other benefits to which such rating might entitle him, regardless of any rating which any rating schedule might designate for such specific disability or disabilities. H. R. 2860, introduced by Representative Allen, Louisiana, proposes to authorize a federal appropriation of \$450,000 to construct an addition to the existing United States Veterans' Administration Facility at Alexandria, La., for the care and treatment of general medical, surgical and neuropsychiatric disabilities. H. R. 2945, introduced by Representative Coffee, Washington, proposes to amend the Longshoremen's and Harbor Workers' Compensation Act to extend its benefits to boommen and raftmen employed in lumbering operations on navigable waters of the United States. H. R. 2987, introduced by Representative Kilday, Texas, proposes to define the term employee as used in the Social Security Act to exclude an officer of a corporation exempt from income tax under the provisions of section 101 of the Internal Revenue Code who does not receive compensation for his services. H. R. 3010, introduced by Representative Beckworth, Texas, proposes to authorize for each fiscal year beginning with the fiscal year ending June 30, 1941 a federal appropriation sufficient to provide grants for the states for assistance to needy incapacitated adults who are 18 years of age or more and are permanently incapable of self support by reason of a physical disability or defect, other than mental. H. R. 3100, introduced by Representative Walter, Pennsylvania, provides that in any case in which proof of age or of place of birth or proof of a death is required in the administration of any law of the United States the agency administering such law shall accept as proof of age, or of place of birth, or of proof of a death, any document purporting to show such fact when it is duly certified as a correct copy of an original document on file with the official custodian of records where the birth or death occurred if such original document has met all the requirements of the laws of the state where such birth or death occurred.

STATE MEDICAL LEGISLATION

Arizona

Bills Introduced.—H. 1 proposes to create a state department of health to succeed to and be vested with the duties and powers heretofore by law vested in and imposed on the state board of health, the superintendent of public health, the state registrar of vital statistics, the supervisor of public health nursing, the state laboratory, the director of the state laboratory, the board of regents of the University of Arizona with respect to the state laboratory and the director thereof, and the state dairy commissioner. The department is to be divided into the following divisions and bureaus: division of local health administration, division of maternal and child health, division of vital statistics, division of sanitary engineering, state laboratory and division of public health nursing. The department is to be headed by a superintendent of public health, who is to be appointed by the state board of health. The state board of health, which is to advise the superintendent in the performance of his duties and is to formulate general policies affecting the public health, is to consist of five members, appointed by the governor for four year terms. H. 9 proposes to require every physician or other person engaged in the antepartum care of a pregnant woman, or attending a pregnant woman at the time of delivery, to obtain a specimen of her blood not less than ten days after the first professional visit and to submit the specimen to an approved laboratory for a standard laboratory test for syphilis. S. 40 proposes to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of the certificate of a licensed practitioner of medicine and surgery that (1) the party has been subjected to a thorough physical examination, tuberculin test and adequate laboratory tests to determine the presence of gonorrhea or syphilis and (2) the party is free from infectious, contagious and venereal disease. H. 43 proposes to make it unlawful for any hospital exempted from taxation, in whole or in part, to refuse to render promptly the necessary

medical treatment to any person in case of accident or injury, or in case of any diseased, infected or abnormal physical condition which is likely to cause death or severe injury.

Arkansas

Bills Introduced.—S. 60 proposes to enact a new optometry practice act. The bill states that "The practice of Optometry is hereby declared to be a learned profession, and the same rights, powers and duties are hereby declared to attach thereto as attach to other learned professions. The profession and the practice of Optometry is hereby defined to be the employment of any method or means other than the use of drugs, medicine or surgery for the analysis of any optical defect, deficiency or deformity, visual or muscular anomaly of the visual functions, or the use of scientific instruments to train the visual system." The bill proposes to prohibit certain types of advertising and practices in connection with the practice of optometry and is so worded as to include licensed physicians and surgeons within the prohibitions. However, a section of the bill provides that nothing in the act, with the exception of the prohibited advertising and practices referred to, shall apply to physicians and surgeons. H. 84 proposes so to amend the basic science act as to exempt chiropractors from its provisions. H. 143 proposes to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of a physician's certificate that the party is free from venereal disease and is not idiotic, feebleminded, imbecilic, epileptic or insane as nearly as can be determined by a thorough physical examination and such standard microscopic and serologic tests as are necessary for the discovery of venereal disease. H. 151 proposes that the basic science act "shall not apply to any person who was a resident practitioner of Chiropractic on January 15, 1940, and to whom a license to practice chiropractic was issued by the State Board of Chiropractic Examiners prior to said date." The bill also proposes that it shall be unlawful for any person engaged in the practice of chiropractic to advertise in any manner. S. 73 proposes to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of a certificate of a licensed physician stating that the party is free from any venereal disease and is not idiotic, feebleminded, imbecilic, epileptic or insane as nearly as can be determined by a thorough physical examination and by standard microscopic and serologic tests. S. 81 proposes to require every physician attending a pregnant woman for conditions relating to pregnancy during gestation or at delivery, to take or cause to be taken a sample of her blood at the time of the first examination and to submit the sample to an approved laboratory for a standard serologic test for syphilis.

California

Bills Introduced.—A. 350, to amend the law permitting the court in any civil or criminal proceeding to appoint one or more expert witnesses to investigate and testify concerning matters on which the court deems expert evidence advisable, proposes to give this right also to juvenile courts. A. 455 proposes to exempt from execution or attachment the tools or implements of a chiropodist. A. 563, to amend the laws relating to nonprofit corporations, proposes to permit a nonprofit corporation to be formed for rendering services "including professional services of persons licensed under any chapter of the Business and Professions Code." The bill proposes that a nonprofit corporation formed for the purpose of defraying the cost of professional services may have three or more classes of members and must offer membership therein and an opportunity to render professional services on a uniform basis to all regularly licensed members of the particular profession or professions concerned. A. 596 proposes to repeal Statutes, 1937, ch. 804, regulating the conduct of clinical laboratories and to enact in its place a new chapter in division 2 of the Business and Professions Code, to be entitled "Clinical Laboratory Technology." This bill proposes to make it unlawful for any person to make any test or examination in a clinical laboratory which requires the application of one or more of the fundamental sciences, such as bacteriology, biochemistry, serology and parasitology, unless the person is either a licensed physician and surgeon, is a licensed clinical laboratory technician or is a licensed clinical technologist. The bill proposes to set up certain educational standards with

respect to persons desiring to be clinical laboratory technologists, defined by the bill as persons engaging in the work and direction of clinical laboratories. The bill also sets up certain standards for a person desiring to act as a clinical laboratory technician, defined as any person other than a physician and surgeon who, under the direction of a clinical laboratory technologist or a physician and surgeon, performs the technical procedure called for in a clinical laboratory. The bill defines clinical laboratory as any place, establishment or institution organized and operated for the practical application of one or more of the fundamental sciences by the use of specialized apparatus, equipment and methods for the purpose of obtaining scientific data which may be used as an aid to ascertain the presence, progress and source of disease. S. 302 proposes that any action by or on behalf of a minor for personal injuries sustained prior to or in the course of his birth may be brought within four years from the date of injury and that the time such minor is under any disability shall not be excluded in computing the time limited for the commencement of the action. A. 503, to amend the medical practice act, proposes that in grading the examination questions of an applicant for a license to practice medicine a credit of 1 per cent must be granted on the applicant's general average for each year of actual licensed practice in the United States and Canada, which credit shall not exceed 10 points on such general average. A. 562 proposes that any nonprofit membership corporation operating a medical and surgical service plan with participation available to all duly licensed doctors of medicine may make, enter into and perform medical and surgical service contracts and may contract with any agency or instrumentality of the United States in aid or furtherance of such contracts, and may accept, receive and administer, in trust, funds directly or indirectly made available by any agency or instrumentality of the United States. Any such corporation in the administration and trust of such funds is to be deemed an instrumentality of the United States. A. 723 proposes to exempt from tax the gross receipts from sales of and the storage, use or other consumption in this state of medicines and drugs. A. 1073, to amend the laws relating to the adulteration, mislabeling, misbranding, advertising and sale of drugs and devices, proposes that the term "drugs" shall include products sold for their vitamin potency when medicinal claims are made for such products. The bill also proposes that a drug shall be deemed to be misbranded if it does not state on its label the kind and quantity or proportion of any iodides, phenol, ephedrine, epinephrine or amphetamine. The bill also proposes that a drug shall be deemed to be misbranded if it contains any quantity of thyroid unless it is sold on a written prescription of a licensed physician, dentist or veterinarian. S. 645 proposes to provide a system of compulsory health insurance to be administered by the agency administering the state unemployment insurance system. S. 1065 proposes to make it the duty of any physician, midwife, nurse, maternity home or hospital or any person attending or assisting in any way at childbirth to treat both cycs of the infant within two hours after birth with a "prophylactic efficient" treatment.

Connecticut

Bills Introduced.—S. 34 proposes to enact a separate massage practice act and to create a board of examiners in massage to examine and license applicants for licenses to practice massage. The bill proposes to define massage as "any process or action of conjoint motion and pressure applied by hand, such as rubbing, stroking, kneading, tapping or other similar manipulation, with or without the application of creams, lotions or liniments or the use of hand vibrators or rollers to any part of the human body for the purpose of relieving pains, aches, stiffness or soreness of muscles or for the purpose of inducing blood circulation or reducing conditions of obesity, or for any other remedial purpose, including the use of any and all other manual means such as physical exercises for the conditioning of the human body." H. 77 proposes to establish a Council on Mental Health to direct and coordinate the activities of institutions concerned with the public care of the mentally sick, mentally defective, epileptic and inebriate and to study the needs of the state and to initiate and direct programs of prevention and follow-up activities outside the institutions. H. 32 proposes to appropriate \$50,000 to the department of health to be used for the study of cancer and the maintenance of diagnostic and treatment clinics for the

biennium ending June 30, 1943. H. 79 proposes to create a Commission on the Care of the Chronically Sick and Infirm. The commission is to study the extent of the needs for the care of the chronically ill and formulate policies with respect to the type of disease and the persons for whom such care shall be provided. H. 126, to amend the laws regulating the practice of the healing arts, proposes, among other things, (1) certain additional causes for the revocation or suspension of licenses; (2) that disciplinary proceedings be instituted by filing written charges by the state department of health with the examining board representing the branch of the healing art practiced by the practitioner; (3) that disciplinary action may be had by a majority vote of the affected examining board, rather than by unanimous vote as the law now provides; (4) that applicants for licenses to practice any form of the healing art must be citizens of the United States; and (5) that applicants for licenses to practice any form of the healing art before beginning the study of medicine must have completed a one year's college course, including courses in chemistry, physics and general biology, and after July 1, 1947 must have completed a two years' college course. S. 35 proposes to create a state department of mental health to consist of a commissioner of mental health and a mental health council. The commissioner is to be given the power to inspect state institutions for the mentally sick, mentally defective and epileptic and to coordinate the activities of such institutions. The mental health council is to establish districts from which mentally ill persons in need of state hospital care can be admitted and shall establish standards for, investigate, license and inspect private institutions for the care and treatment of the mentally sick, mentally defective and epileptic. S. 79 proposes to transfer the bureau of occupational diseases from the department of health to the department of labor and factory inspection and to designate it as the division of industrial health. The bill proposes to require the division of industrial health to investigate industrial establishments and to make tests for the purpose of determining whether the health of the employees is endangered by any conditions of employment. The chief of the division is to prescribe and recommend means for eliminating, obviating or reducing industrial health hazards. The division is also required to publish from time to time the threshold limits, or limits of tolerance, for injurious dusts, mists, fumes, vapors, gases and materials in work places. The bill also requires every physician who has knowledge of any person whom he believes to be suffering from occupational poisoning or occupational disease to report the facts to the division of industrial health. S. 37, to amend the laws regulating the operation of institutions for the treatment of detention of insane persons or of persons suffering from other abnormal mental or nervous conditions, proposes to vest the licensing of such institutions in the state department of mental health. H. 76, to amend the law which prohibits a hospital receiving a state appropriation from receiving more than \$8 a week for the care of any 1 patient whose expenses are paid by the state or any subdivision thereof proposes that "if the total of the expenses incurred by the State for hospital care during any fiscal period at said rate of eight dollars a week plus the annual appropriation of the General Assembly to such hospital shall not be sufficient to pay such hospital for such care at the rate of five dollars per day for each such patient, such hospital shall be paid the deficiency by the State." H. 127, to amend the law relating to the qualifications of the commissioner of health, proposes to require the commissioner not only to be a graduate of an acceptable medical college and to have had at least five years of experience in actual practice but also to have had a minimum of one year of university graduate instruction in public health as evidenced by a certificate of graduation or a degree in public health. H. 82, to amend the law regulating the operation of institutions for the treatment or detention of the insane or persons suffering from other abnormal nervous or mental conditions, proposes, apparently, to vest the administration of the law in the State Council on Mental Health. H. 128, to amend the law relating to the tuberculosis commission, proposes that the commission shall cause instruction of the public in rules of living essential to the suppression of tuberculosis and shall provide and maintain within or apart from the state sanatorium facilities personnel for the detection of tuberculosis in its early stages, and for the rehabilitation of the

tuberculous. S. 231 and H. 367 propose to appropriate \$50,000 to the department of health for the study of cancer and the maintenance of diagnostic and treatment clinics for the biennium ending June 30, 1943. H. 184 proposes to enact a separate physiotherapy practice act and to create an independent board of examiners for physiotherapy to examine and license applicants for licenses to practice as physiotherapy technicians. The bill proposes that "The practice of physiotherapy technique is defined as (a) The performing, for compensation received or expected under the direction of a licensed physician, or any professional service requiring special education, knowledge and skill in the physiotherapy treatment of injury, disease or deformity; (b) Physiotherapy is understood to be the treatment of patients by physical means including the various modalities of electricity; light; heat; massage; exercise and water." S. 65 proposes that any person charged with driving a motor vehicle while intoxicated may demand a blood or urinal test or both to determine the amount of alcohol in his blood system and that the results of such tests shall be admissible as evidence at the trial of the accused person. H. 732 proposes that \$2.50 of the fee paid by each motor vehicle operator shall be placed in a fund to be used to defray the expenses of hospitalization and physicians' fees in cases of injuries caused by motor vehicle accidents.

Delaware

Bills Introduced.—H. Res. 1 proposes to abolish the office of coroner in the respective counties. H. 6 proposes to establish the office of medical examiner for the state of Delaware to assume the functions, among other things, of the coroner's physician of each county. The medical examiner, the bill proposes, must be a licensed physician and a skilled pathologist, microscopist and toxicologist. The bill proposes that whenever in the state any person shall die from criminal violence, by casualty, by suicide, suddenly when in apparent health or when unattended by a licensed physician, the medical examiner shall be notified by the person or persons having knowledge of the facts. Immediately on receipt of such notification the medical examiner or a deputy or assistant must take charge of the dead body and investigate the essential facts concerning the circumstances of death. If the cause of death is established beyond doubt, the medical examiner shall so report to the attorney general; but if an autopsy is necessary the medical examiner shall perform it and forward a detailed description of his findings to the attorney general.

Georgia

Bills Introduced.—S. 55, to amend the law authorizing the operation of nonprofit hospital service plan corporations, proposes that (1) all plans offered by such corporations must afford the subscriber and his dependents the right to select the services of any approved hospital in the state and (2) each such corporation shall be authorized to accept applications for memberships and to issue contracts only to persons residing in counties in which the hospital service plan of such corporation shall have been approved by the county medical society of that county. H. 12 and S. 10 propose to create a state hospital authority to consist of the governor, the state auditor and the attorney general. The state hospital authority is to succeed to and be vested with all the powers, duties, obligations and liabilities vested in or imposed on the state hospital authority created by the act of Feb. 1, 1939. H. 122, to amend the workmen's compensation act, proposes to make compensable disability arising from any one of some twenty-five stated occupational diseases. H. 201, to amend the chiropractic practice act, proposes (1) that "Chiropractors who have complied with the provisions of this Chapter shall have the right to adjust patients according to specific chiropractic methods, shall have the right to use air, light, heat, water and exercise in the treatment of disease, and shall observe State, municipal and public health regulations, sign death and health certificates, reporting to the proper health officers the same as other practitioners. Chiropractors shall not prescribe or administer medicine to patients, perform surgery, nor practice obstetrics or osteopathy;" (2) to define chiropractic to be "a drugless health science, which teaches the art and philosophy of locating and correcting, by scientific methods, any interference to nerve transmission, including hygienic, sanitary, dietary and other natural and physical measures which promote

health and prevent disease. It also includes the use of electricity, X-ray photograph, but the X-ray shall not be used for therapeutical purposes," and (3) to require chiropractors to renew their licenses annually and to condition such renewal on the presentation by each licentiate of evidence that he has attended in the preceding year at least one of the two "educational" programs conducted by the Georgia Chiropractic Association.

Illinois

Bills Introduced.—S. 10 proposes to recodify the cities and villages act. Among other things, the bill proposes that in hospitals established by cities of less than one hundred thousand population "All physicians who are recognized as legal practitioners by the Department of Registration and Education shall have equal privileges in treating patients in such a hospital." H. 51 proposes to require every person employed in any capacity in any place in which food is sold for consumption on the premises to submit annually to an examination by the Department of Public Health to determine whether he is free from communicable tuberculosis or venereal disease.

Iowa

Bills Introduced.—S. 95 and H. 122 propose to enact a new pharmacy practice act and to limit the retail sale and distribution of drugs and medicines to pharmacies or drug stores operating under licenses issued by virtue of the act. The bill proposes, however, that licensed physicians, osteopathic "physicians," dentists and veterinarians may personally supply their own patients with such drugs and medicines as they may prescribe, provided they prescribe and dispense in compliance with the practice acts under which they are licensed. S. 157, to amend the chiropractic practice act, proposes, among other things, (1) to define the practice of chiropractic as "the adjustment of articulations of the spine and other incidental adjustments, and shall include the right to use air, light, heat, cold water, diet and exercise, in the treatment of disease, except as hereinafter specifically prohibited," and (2) to provide that chiropractors shall be entitled to all the rights and privileges of physicians and surgeons and shall be subject to all the duties and obligations of physicians and surgeons so far as they are not in conflict with the provisions of the chiropractic practice act and specially to prohibit a chiropractor "from practicing operative surgery, cautery, electro-coagulation, radium in any form, general hyperpyrexia, osteopathy, optometry, obstetrics, x-ray treatment, or administering or prescribing any drug or medicine included in materia medica." H. 35 proposes to authorize any law-enforcing official to direct the taking of a blood, urine, breath or body substance test to determine intoxication of any person under arrest for any crime in which the issue of intoxication may arise or in which intoxication may be the subject of the charge. Presumably the results of any test so made are to be admissible in evidence in subsequent court proceedings.

Kansas

Bill Introduced.—H. 31, to supplement the chiropractic practice act, proposes to condition the annual renewal of a license to practice chiropractic on attendance by the licentiate in the preceding year at the educational program conducted by the Kansas chiropractors' association or a postgraduate course equivalent thereto.

Michigan

Bills Introduced.—S. 66 proposes to make compensable any and all occupational diseases arising out of and in the course of employment. The bill proposes to define "occupational disease" as "a disease or disability which is due to causes and conditions which are characteristic of and peculiar to a particular trade, occupation, process or employment." S. 71 proposes that whenever in any proceedings before any court, board or commission, or other public body or officer, an order is made requiring a person to submit to a physical examination, the order shall also provide that the attorney for that person may be present at such physical examination. H. 84 proposes a supplementary appropriation of \$435,452.13 to the Michigan crippled children commission for the fiscal year ending June 30, 1941. S. 79 proposes to make it the duty of every hospital to render necessary first aid and other medical or surgical treatment to any person injured in an accident.

Minnesota

Bill Passed.—H. 83 passed the house, February 5, proposing to authorize the operation of nonprofit hospital service plan corporations by which hospital service will be provided by hospitals with which such corporations have contracts to persons who become subscribers to such plans. The bill specifically provides that nothing contained in it shall authorize any person, association or corporation to engage in any manner in the practice of healing.

Montana

Bills Introduced.—H. 50 proposes to repeal the existing law regulating the manufacture and distribution of foods and drugs and to enact a law regulating the manufacture, sale, distribution or advertising of foods, drugs, cosmetics and therapeutic devices. H. 72, to amend those provisions of the workmen's compensation act requiring an employer to furnish to his injured employees during the first six months after the happening of an industrial injury necessary medical and hospital services not exceeding \$500, proposes that the period and amount during and for which the employer may be liable may be extended in the discretion of the administrative board. S. 24 proposes to require an applicant for a license to practice any form of the healing art as a condition precedent to examination and licensure by his respective licensing board to pass examinations in anatomy, physiology, chemistry, bacteriology and pathology before a board of basic sciences, which is to consist of five members "none of whom shall have graduated from any school of healing art, and who shall be members of the faculty of the University of Montana at Missoula Montana State College at Bozeman." S. 27 proposes to make it unlawful "for any person, firm, corporation or association to sell, furnish, or give away, or offer to sell, furnish or give away, or have in his possession Peyote (Pellote), Anhalonium or any compound, derivative, or preparation thereof; provided that the terms of this act shall not apply to transporting, possessing or using said peyote for religious sacramental purposes within the boundaries of an Indian reservation." H. 74, to amend the workmen's compensation act, proposes in effect to make compensable the disablement from silicosis of any employee in any occupation wherein there is an exposure to silica dust. The bill proposes to define "silicosis" as a "fibrotic condition of the lungs caused by inhalation of silica dust sufficient to render the workman incapable of following his regular occupation."

New York

Bills Introduced.—A. 442 proposes to authorize the establishment and operation of a state cancer hospital at Utica. Patients who are able to pay for the care and treatment may be admitted to such hospital but preference is to be given to those who are unable to pay in whole or in part for their care and treatment. A. 501, to amend the laws authorizing the operation of medical service plan corporations and hospital service plan corporations, proposes to prohibit medical expense indemnity corporations and hospital service corporations from employing solicitors or accepting business from brokers on a commission basis. The bill proposes that all solicitors must be paid on a salary basis only. A. 527 proposes to enact a separate chiropractic practice act and to create a board of chiropractic examiners to examine and license applicants for licenses to practice chiropractic. The bill proposes that the "Science of chiropractic" means "the art of palpating, manipulating and adjusting the human spinal column by hand only. It excludes operative surgery and the prescription or use of drugs or medicines, the reduction of fractures, obstetrics, osteopathy and physio-therapy."

North Carolina

Bill Introduced.—S. 67 proposes a procedure whereby hospitals may be reimbursed by the state for care they have rendered indigent persons injured in motor vehicle accidents.

Ohio

Bill Introduced.—H. 58 proposes that "In an action or proceeding where the physical condition of a party is in issue the court may, upon application of an adverse party, order said party to submit to a physical examination by a licensed physician approved by the court."

Oregon

Bills Introduced.—S. 62 proposes a new act to provide for the making, keeping and use of vital statistics and for securing complete data pertaining to births, deaths, stillbirths, marriages, divorces and annulments of marriages. H. 79 proposes a new act regulating the manufacture, sale, distribution and advertising of foods. S. 117, to amend the chiropractic practice act, proposes, among other things, to define chiropractic as "that system of adjusting with the hand or hands the articulations of the bony framework and soft tissue of the human body, and the employment and practice of physiotherapy, electrotherapy and hydrotherapy for the treatment, cure or mitigation of human disease; provided, that no person practicing under this act shall write prescriptions for, or dispense drugs, practice optometry, or naturopathy, or do major surgery." The bill also proposes to eliminate a provision in the present act providing that it shall not be construed so as to interfere with or prevent the practice of, or use of massage, Swedish movement, physical culture, neuropathy, naturopathy or other natural methods requiring the use of hand or hands. The bill also proposes to require an applicant for a license to have graduated from "an approved chiropractic school or college requiring for graduation a period of actual attendance equivalent not less than nine months for four years." Under the present law the required attendance at a chiropractic school is only three years of nine months each. H. J. R. 6 proposes to request the appointment of an interim commission of at least three qualified persons to make a complete survey of the teachings, staff, laboratory facilities, student bodies, physical facilities and type of training afforded in osteopathic schools, and of at least "one class A medical school." H. 98 proposes a procedure whereby hospitals may be reimbursed by the state for care rendered indigent persons injured in motor vehicle accidents. H. 103 proposes to require every licensed physician attending a pregnant woman for conditions relating to pregnancy during the period of gestation or at the time of delivery, to take or cause to be taken at the time of the first professional visit a sample of her blood and to submit the sample to an approved laboratory for a standard test for syphilis. H. 197, to amend those provisions of the medical practice act relating to the practice of osteopathy, proposes (1) to create a separate examining board for osteopaths and (2) to authorize the separate osteopathic examining board to examine and license applicants for licenses to practice osteopathy and to institute and determine proceedings looking toward the revocation of suspension of a license to practice.

Pennsylvania

Bill Introduced.—S. 51 proposes to authorize directors of school districts of the first class to furnish food, including milk, to poor school children attending their schools.

Rhode Island

Bill Introduced.—S. 51, to amend the workmen's compensation act, proposes to limit an employer's liability for reasonable medical, dental and hospital services for an employee injured from an industrial accident to \$500. If no hospital services are necessary, the extent of employer's liability is to be \$300. The present law limits the employer's liability in this respect to \$200 or \$250 according to circumstances.

South Dakota

Bill Introduced.—S. 73, to supplement the osteopathic practice act, proposes to permit the board of osteopathic examiners to license persons possessing the qualifications stated in the bill to practice surgery in all its branches. An osteopath is eligible to receive such a license if in addition to the qualifications now required by the osteopathic practice act he has served at least two years as an intern in a hospital at which general surgery is performed and which is approved by the osteopathic board and if he passes examinations to be given by the osteopathic board in surgical diagnosis, surgical technique and such other related subjects as the board may see fit to require. Even though an applicant for such an extended license may not have served an internship as above specified the board in its discretion may examine the applicant if he presents evidence of experience, post graduate work and special study in surgery.

Tennessee

Bills Introduced.—H. 426 and S. 314 propose to require applicants for licenses to practice any form of the healing art, as a condition precedent to examination and licensure by their respective licensing boards to pass examinations in anatomy, physiology, chemistry, bacteriology and pathology before a board of examiners in the basic sciences. The board is to consist of five persons appointed by the governor. "No one shall be eligible for appointment as a member of the Board who is at the time of his appointment or has ever been actively engaged in the practice of the healing art or any branch thereof, and wherever possible, members of the Board shall be selected who are not engaged in teaching in any schools for education in the healing arts." S. 314 passed the senate February 5. S. 265 proposes a new act to provide for the making, keeping and use of vital statistics.

Texas

Bill Introduced.—S. 27, to amend the motor vehicles code, proposes that in the trial of any person charged with driving while intoxicated the court shall admit in evidence the result of any chemical test or analysis of the breath, urine, blood or other bodily substance of the defendant made at the time or within three hours after the commission of the alleged offense to show the amount of alcohol in the defendant's blood. The bill further proposes that any peace officer on arresting a person for driving while intoxicated may have a chemical test or analysis made of the breath, urine, blood or other bodily substance of such person within three hours after said arrest, either with or without the consent of the accused.

Utah

Bills Introduced.—S. 71 proposes that "Before any person shall issue any marriage license, each applicant therefor shall file with him a certificate from a licensed physician and surgeon which certificate shall state that the applicant has been given an examination, including a standard serological test for syphilis, made not more than thirty days prior to the date of issuance of such license and that in the opinion of such physician and surgeon, the person either is not infected with syphilis or other venereal

disease, or if so infected, is not in a stage of such disease which is or which may become communicable." S. 92 proposes to require applicants for licenses to practice any form of the healing art, as a condition precedent to examination and licensure by their respective licensing boards, to pass examinations in anatomy, physiology, pathology, bacteriology and chemistry, to be given by a committee of basic science examiners. The committee is to consist of five members, each of whom must be a full time paid professor, or associate or assistant professor, not actively engaged in the practice of the healing art but who is teaching a basic science. S. 72 proposes to require every licensed physician attending a pregnant or recently delivered woman for conditions relating to pregnancy to take or cause to be taken, at the time of the first examination or within ten days thereafter, a sample of her blood and to submit the sample to an approved laboratory for standard serologic tests for syphilis. H. 45 proposes to authorize the organization and operation of health cooperative associations to provide medical, dental, hospital and related services to members of such organizations.

West Virginia

Bill Introduced.—H. 95 proposes that whenever it is relevant in any action to determine the parentage or identity of any person or body, the court may direct any party to the action and the child of any such party and any other person involved to submit to one or more blood grouping tests to determine whether the defendant can be excluded as being the father of the child.

Wyoming

Bill Passed.—H. 40 passed the House February 1, proposing to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of a certificate from a licensed physician stating that the party has been given such examination, including a standard serologic test for syphilis, performed not more than ten days prior to the date of issuance of such license, and that in the opinion of the physician the party is either not infected with syphilis or other venereal disease or is not in a state of that disease which may become communicable.

OFFICIAL NOTES

RADIO BROADCASTS

"Doctors at Work" is the title of the sixth annual series of dramatized radio programs being presented by the American Medical Association and the National Broadcasting Company.

The series opened Wednesday, November 13, and will run for thirty consecutive weeks, closing with a broadcast from the A. M. A. meeting at Cleveland on June 4. The program is scheduled for 10:30 p. m. eastern standard time (9:30 central, 8:30 mountain, 7:30 Pacific time) over the Blue network, other N. B. C. stations and Canadian stations.

The programs are broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations, and no revenue is derived from the programs. Therefore, local stations may or may not take the programs, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

Some radio stations may be unable to broadcast the program at the regular scheduled time and may transcribe and broadcast it at another hour or even on another day. It is advisable

therefore to verify the time by reference to local newspapers or by telephoning the local Blue network stations.

The programs will dramatize what modern medicine offers the individual in the way of opportunities for better health and the more successful treatment of disease. Incidental to this main theme, the programs will explain the characteristics of the different fields of modern medicine and its specialties.

Descriptive posters for local distribution may be had gratis from the Bureau of Health Education, American Medical Association, 535 North Dearborn Street, Chicago. Program titles will be announced weekly in THE JOURNAL and monthly in *Hygeia*, the Health Magazine.

Tickets are available for each broadcast. Address the Bureau of Health Education, American Medical Association, 535 North Dearborn Street, Chicago. Tickets are free, but a stamped, self-addressed envelop should accompany requests.

The next three programs to be broadcast, together with their dates and titles, are as follows:

February 19. One Man's Poison.
February 26. Exploring Man's Mind.
March 5. Fit to Fight.

WOMAN'S AUXILIARY

Arkansas

The Jefferson County auxiliary was addressed on October 11 by Mrs. Alfred Hathcock of Fayetteville, president of the Woman's Auxiliary to the Arkansas Medical Society.

The Sebastian County auxiliary met, October 14, at the home of Mrs. Ruth Moss Carroll and voted to contribute \$10 to the state student loan fund and to renew complimentary subscriptions

of *Hygeia* to the girls' club, Rosalie Tilles Children's Home, Young Women's Christian Association and Carnegie Library.

Mrs. Hathcock was guest of honor when the Sevier County auxiliary met at the home of Miss Eleanor Park. Other state officers present were Mrs. Ralph Cross, third vice president and chairman of *Hygeia*; Mrs. Fount Richardson, secretary, and Mrs. Pierre Redman, parliamentarian. At the October 15 meet-

ing at the home of Mrs. C. E. Kitchens it was voted to make a contribution to the library fund for tuberculosis hospitals.

The auxiliary to the Bowie-Miller Counties Medical Society was addressed, October 25, by Mrs. William Hibbitts, of Texarkana, and Mrs. Alfred Hathcock, of Fayetteville, presidents respectively of the Texas and the Arkansas auxiliaries.

The Washington County Medical Auxiliary met with Mrs. Fount Richardson for a work meeting, October 18. Mrs. Alfred Hathcock presented the *Bulletin* of the American Medical Association auxiliary and urged that as many members as possible subscribe.

The Pulaski County auxiliary met at the home of Mrs. A. C. Shipp in October. The meeting was attended by fifty, thirteen of whom were new members. The student loan fund committee reported a cookie sale at which they made \$14.

At the November meeting of the auxiliary to the Ouachita County Medical Society Mrs. Arthur A. Herold, national legislative chairman, spoke on medical legislation. Mrs. C. W. Garrison spoke on the work of the auxiliary.

The Woman's Auxiliary to the Washington County Medical Society met in November at the home of Mrs. Friedman Sisco in Springdale. Twenty wash cloths were made for the WPA Nursery School at Fayetteville. Members decided to sew for the Red Cross. Mrs. H. H. Howze read a paper on "Hemophilia: One of the Causes for Political Upheaval Throughout the Centuries."

Mrs. A. A. Herold, Shreveport, La., national legislative chairman of the auxiliary, was a visitor at the meeting of the auxiliary to the Bowie-Miller County Medical Society at the home of Mrs. Harry E. Murry in Texarkana, November 22. Mrs. Herold spoke on the importance of health legislation and the part that physicians are taking in the preparedness program.

California

The Alameda County auxiliary opened the fall season with a reception at the Claremont Country Club, Dr. Gertrude Moore being the honored guest.

The Fresno County auxiliary has been approached by the local junior chamber of commerce to help in establishing an abatement district for mosquito control. The auxiliary has formed a committee for Allied relief.

The auxiliary to the Los Angeles County Medical Society had an attendance of one hundred members at a recent meeting at which Mrs. Robert Millikan's talk, "Trailing a Scientist Through India," was thoroughly enjoyed. Mrs. William C. Boeck gave an account of the state board meeting in Alameda County.

Dr. Norris R. Jones, president of the Sacramento County Medical Society, complimented forty members of its auxiliary on the splendid work accomplished during the past year. Health education will be stressed by the membership of the San Diego County auxiliary this year, arrangements having been made to assign speakers on medical topics to appear before the Girl Scouts, the Girl Reserves, the Boy Scouts, the Campfire Girls and the Parent-Teacher groups. Speakers will address adolescent boys, adolescent girls and a mixed group of adults at "Neighborhood House." Work is well under way on the survey, being conducted by the public relations committee, of which Mrs. Walton Lewis is chairman, which will produce a valuable index system of the various organizations in San Diego. More than two hundred and twenty-five organizations have been contacted, and information has been obtained as to the number of members, whether or not they have a health program and whether or not they would desire or permit speakers to appear before them. The auxiliary is also sponsoring a scholarship loan to assist worthy students in paying their expenses in medical schools.

The San Francisco auxiliary has decided to assist the British War Relief by giving a fashion talk and demonstration, the proceeds to supply medicine to the children of the British War Relief. Money recently raised for the Scholarship Fund has been sent to the universities of Stanford and California.

The Stanislaus auxiliary has embarked on a new project: It deals with occupational therapy for tuberculous patients at the county hospital. The membership will give financial and moral support, as well as help, to collect materials with which to work and will distribute the finished products.

Georgia

Three auxiliaries have recently been organized, those to the Grady County Medical Society, the Cobb County Medical Society and the Seventh District Medical Society. Plans were made to organize county auxiliaries in Whitfield, Floyd and Gordon counties.

Mrs. C. S. Pittman, of Tifton, was elected president of the auxiliary to the Second District Medical Society at a meeting in Cairo. Dr. J. A. Redfearn, of Albany, talked on the tuberculosis situation in Georgia, following which Mrs. H. G. Banister, of Ila, state president, talked on "Mobilization to Present-Day Conditions." Mrs. G. L. Loden, of Colbert, state chairman of health films, told of plans to show health films in all counties of the state. Members were guests of the doctors of the second district at a banquet.

The Woman's Auxiliary to the Ninth District Medical Association met at Canton. Mrs. H. G. Banister, of Ila, president of the Woman's Auxiliary to the Medical Association of Georgia, discussed the work to be undertaken during the year. It was reported that Gwinnett County had recently organized an auxiliary, the district now having seven counties organized, others being Jackson, Barrow, Habersham, Stephens, Cherokee and Pickens. The feature of the program was an illustrated lecture by Dr. Hugh Hailey, of Atlanta, on "Inflammation of the Skin Caused by Cosmetics."

Dr. Milford B. Hatcher talked on appendicitis at a recent meeting of the Woman's Auxiliary to the Bibb County Medical Society.

Illinois

The Woman's Auxiliary to the Chicago Medical Society held its annual "Public Relations Day" meeting, Wednesday, November 6, at the American Medical Association Building. Mrs. W. C. Bornemeier, president; Mrs. H. P. Jenkins, public relations chairman, and Mrs. John Soukup, program chairman, conducted the meeting. Three hundred members and guests representing the Federated Women's Clubs, Parent Teachers' Association and League of Women Voters attended. Dr. Morris Fishbein, Editor of *THE JOURNAL*, addressed the group on current topics of interest. After discussing the activities of the American Medical Association, he told of some of the fallacies of socialized medicine and pointed out the great interest which has been developed among lay organizations concerning this problem.

A staff of well informed guides then conducted the tour of the building, which ended in the dining room where tea was served. Envelops containing a copy of *Hygeia*, the booklet "Priceless Heritage," circulars concerning the women's field army and their drive for the control of cancer and a list of services offered lay organizations by the Educational Committee of the Illinois State Medical Society were distributed to the guests.

The Adams County medical auxiliary met, November 12, in Quincy with Mrs. J. F. Ross, the president, presiding. In the absence of Dr. R. A. Harris, Mrs. Harris read his paper, which dealt with some phases of the history of medicine, with emphasis on anesthesia. The November issue of *Hygeia* was reviewed and discussed.

The Peoria County auxiliary met at the Peoria Municipal Tuberculosis Sanitarium, November 12, with thirty-five members present. A tour of the institution was followed by a dinner. After the business meeting, Miss Zoe Velde, secretary of the Peoria tuberculosis Christmas seal sale, gave a short talk, and Dr. Max Pollak spoke on the Peoria Municipal Tuberculosis Sanitarium.

The woman's auxiliary to the north side branch of the Cook County Medical Society met in November at the Y. W. C. A. at Oak and Dearborn streets. Mrs. Harry Dooley discussed *Hygeia* and the "Benevolence Fund"; \$125 was voted for *Hygeia* subscriptions.

The Irving Park branch was addressed by Dr. W. W. Bauer, director of the Bureau of Health Education of the American Medical Association, on *Hygeia*. Mrs. W. J. Wanninger, national *Hygeia* chairman, Mrs. E. M. Egan, state chairman, and Mrs. C. R. Landis, county chairman, conducted a round table discussion on *Hygeia*.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Society News.—The Northwestern Division of the Medical Association of the State of Alabama was addressed at a meeting in Athens, January 9, by Drs. Wilbur M. Salter, Anniston, on "Training Children in Happiness Habits and Hygiene"; Robert B. Dodson, Cullman, "Anemia"; Alva A. Jackson, Florence, "Conservative Treatment of Gallbladder Disease"; Benjamin F. Morton, Birmingham, "The Problem of the So-Called Neurotic Patient," and Gilbert E. Fisher, Birmingham, "Carcinoma of the Lung."—Dr. James P. Collier, Tuscaloosa, discussed "Peripheral Vascular Diseases" before the Walker County Medical Society on January 10.

Two and a Quarter Million Dollar Hospital Dedicated.—The new Jefferson Hospital, Birmingham, erected at a cost of \$2,250,000, was dedicated on December 29, following a three day "open house." The building, financed by government funds under PWA control, is sixteen stories high with a capacity for 575 patients. In addition there are a nursery and quarters for nurses and interns. The fifth floor is exclusively for maternity patients; the seventh floor is given over to eleven operating rooms and laboratories. One floor is designed for communicable diseases and divided into three separate and complete units. The fifteenth and sixteenth floors contain living quarters for one hundred and fifty nurses and twenty-five interns and resident doctors.

CALIFORNIA

Bust of Hippocrates Given to School.—A bust of Hippocrates has been presented to the division of medical history and bibliography, University of California Medical School, San Francisco, by Dr. Pan S. Codellas and other members of the Greek colony of the city. Formal presentation was made recently at exercises commemorating the birth of Hippocrates, at which Dean Emeritus Langley Porter presided. The speakers were Drs. William Dock and Frederick L. Reichert of Stanford University School of Medicine, and Drs. Codellas, William J. Kerr, John B. de C. M. Saunders, Salvatore P. Lucia and Chauncey D. Leake, Ph.D., of the California faculty. The bust has been placed in the Crummer Room, where the university's collection on medical history is housed.

Cardiac Convalescent Home.—A group of buildings in the San Fernando Valley near Los Angeles, known as the Mother Cabrini Villa, has been converted into a cardiac convalescent home for girls. The institution, which has a capacity of one hundred, was formerly a "preventorium" for girls between 5 and 15 years of age. The building was erected by the Missionary Sisters of the Sacred Heart in 1920. The change in the type of care was brought about by requests from physicians, and others of southern California, according to the *Bulletin* of the American Heart Association. The girls are accepted regardless of race or creed. The activities of each child are supervised by qualified graduate nurses. Entrance requirements necessitate only that girls with heart disease or potential heart disease between the ages of 5 and 16 years be admitted. Duration of residence will be limited only by the age limit. Admission examination to determine classification is conducted at selected clinics in Los Angeles County. The new convalescent home is partially financed by the Los Angeles Community Chest and because of this the maximum rate for all care of a child while a resident is \$35 a month. At present the California Heart Association is making a survey of rheumatic fever in the state, and the development of convalescent institutions is a part of its major program.

COLORADO

Society News.—Dr. George M. Myers, Pueblo, discussed "Renal Calculi" before the Otero County Medical Society, La Junta, December 12.—The Pueblo County Medical Society was addressed, December 17, on "Current National Activities of Organized Medicine" by Dr. Guy C. Cary, Grand Junction, president-elect, Colorado State Medical Society.—The Colo-

rado Neurological Society was addressed in Pueblo, January 25, by Drs. Thad P. Sears, Denver, on "Carbon Monoxide Psychosis, with Presentation of a Case"; Irvin I. Schatz, Pueblo, "Personal Experiences with Brain Abscesses," and Carl Schwer, Pueblo, "Undiagnosed Psychosis with Somatic Background."

GEORGIA

The L. C. Fischer Awards.—The Fulton County Medical Society announces that the Dr. L. C. Fischer Award for the best original work has been given this year to Dr. Fred F. Rudder, Atlanta. His subject was "A New Apparatus for Administering Intravenous Anesthetic Agents." The award for the best written paper went to Drs. Thomas S. Claiborne and Bernard P. Wolff for their work on "Rheumatic Heart Disease: Post Mortem Studies in Atlanta."

Changes in Health Officers.—Dr. Charles O. Rainey, Camilla, is on leave of absence from the Mitchell County Board of Health to accept a temporary position as area medical officer of the extracountment area for Camp Stewart at Hinesville.—Dr. Irving E. Simmons, formerly director of the Nassau County Health Department in Fernandina, Fla., is the new health officer in Coffee County, with headquarters in Douglas.

ILLINOIS

Society News.—The Macoupin County Medical Society was addressed in Carlinville, January 27, by Drs. G. Henry Mundi, Chicago, on "Ophthalmology in General Practice" and Robinson Bosworth, East St. Louis, "Care and Control of Tuberculosis."—Dr. Frederick M. F. Meixner, Peoria, discussed "Influenza and Respiratory Infections" at a meeting of physicians of Schuyler and Cass counties in Beardstown, January 8.

Chicago

Hospital News.—Dr. Jacob P. Greenhill has been appointed attending physician (office service in obstetrics and gynecology) at Michael Reese Hospital. Promotions on the staff include those of Drs. John S. Coulter to senior attending physician in physical therapy and William H. G. Logan to senior attending surgeon in oral surgery.

Personal.—Dr. John Chornyak, psychiatrist for the Juvenile Court of Pittsburgh, has been chosen medical director of the Illinois Society for Mental Hygiene. He fills the vacancy that occurred in April 1940 when Dr. Conrad S. Sommer became superintendent of the division of mental hospitals in the Illinois Department of Public Welfare.

Society News.—Members of the staff of Evanston Hospital will present the program of the clinical section of the Chicago Heart Association February 20. Among others, Dr. Jay M. Garner, Winnetka, will speak on "Acute Pericarditis with Effusion and Response to Chemotherapy."

Branch Meetings.—The Jackson Park Branch of the Chicago Medical Society was addressed, January 16, by Drs. Ludvig Hektoen on "The Federal Cancer Program" and Bowman C. Crowell, "Influence of Cancer Clinics in Cancer Control."—Dr. Archibald L. Hoyne discussed "Importance of Observation in Diagnosis" before the West Side Branch on January 16.—A surgical symposium on "when not to operate" was presented before the Calumet Branch January 17, by Drs. Harry E. Mock, Lindon Seed and Channing W. Barrett.—The Northwest Branch was addressed by Drs. Francis E. Senear and Robert W. Keeton, February 14, on "Dermatology in Internal Medicine" and "Office Management of Diabetes" respectively.—Dr. Maurice I. Kaplan addressed the Douglas Park Branch, January 21, on "Radiation Therapy of Acute Infection with Special Reference to Osteomyelitis of the Digits."—The North Side Branch was addressed, February 6, by Dr. Russell L. Cecil, New York, on "Recent Advances in the Chemotherapy of Pneumonia."

INDIANA

Clinic Honors Physicians and Observes Anniversary.—The South Bend Clinic, South Bend, observed its twenty-fifth anniversary, January 8, at a dinner in the Hotel LaSalle and honored Drs. Walter H. Baker and Fred R. Clapp, the two remaining original partners of the institution. The clinic was established on Jan. 1, 1916.

State Medical Board.—The following officers of the Indiana State Board of Medical Registration and Examination were reelected at a recent meeting: Drs. Jacob T. Oliphant, Farmersburg, president; Norris E. Harold, Indianapolis, vice

president; Jesse W. Bowers, Fort Wayne, secretary, and William C. Moore, Muncie, treasurer.

Society News.—The Indiana Association for the History of Medicine met jointly with the Indiana History Society in Indianapolis, December 14, at the Indiana State Library. The speakers included Mrs. Olga S. Goldman, Indianapolis, "Biography of Dr. John S. Bobbs"; Dr. Edgar F. Kiser, Indianapolis, "Amos Twitchell's Copy of 'Beaumont's Physiology of Digestion,'" and Dr. Emmet F. Horine, Louisville, Ky., "Daniel Drake and His Contributions to Education."—The Indianapolis Medical Society was addressed January 23 by Drs. Arthur B. Richter on "Patent Ductus Arteriosus—Its Diagnosis and Indication for Surgical Treatment," and Calvin B. Fausset, "Elective Surgery of the Heart and Pericardium." The society devoted its meeting January 21 to a symposium on gynecology and January 14 to one on arthritis.

IOWA

Postgraduate Courses.—The speakers' bureau of the Iowa State Medical Society announces postgraduate medical courses now being conducted throughout the state in cooperation with local medical societies. The Marshall County Medical Society opened its course on January 7, the Boone and Story county medical societies on January 31. The course for the physicians of the Dickinson, Emmet and Clay county medical societies and vicinity will open in Spirit Lake on February 18 with Iowa physicians as the speakers. Out-of-state speakers will conduct the courses in Marshall, Boone and Story counties. Sessions will be held once a month over an eight or nine month period. A series of weekly postgraduate medical lectures is now being planned for the Poweshiek County Medical Society, to be given in October.

LOUISIANA

Personal.—Dr. Robert W. Faulk, Monroe, was guest of honor at the annual banquet of the Ouachita Parish Medical Society in recognition of his more than fifty years service as a physician in the community. He was presented with a plaque as a memento of the occasion.

Changes in Health Units.—Dr. John G. Norris, Farmer-ville, has retired from active practice to take charge of the Union Parish health unit, a position he formerly held.—Dr. Charles W. Reid, Coushatta, has been appointed director of the Red River Parish health unit.

Health Association Changes Name.—The Louisiana Association of Health Officers changed its name to the Louisiana Public Health Association during the annual session in New Orleans, December 11. Officers elected at this meeting include Dr. William W. Knipmeyer, Natchitoches, president, succeeding Dr. Christopher L. Mengis, New Iberia, and Dr. Reuben Alec Brown, New Orleans, secretary-treasurer.

MAINE

Society News.—Dr. James W. Toumey, Boston, discussed "Various Conditions Causing Low Back Pain" before the Cumberland County Medical Society, December 20.—The Kennebec County Medical Association was addressed in Augusta, December 19, by Dr. Albert Warren Stearns, Boston, on "Hypochondria and Hysteria, a Historical Study of the Evolution of Functional Nervous Disease."—Dr. Charles H. Lawrence, Boston, addressed the Penobscot County Medical Association in Bangor, December 17, on "Adolescent Menstrual Disturbances, Their Significance, Diagnosis and Treatment."

MASSACHUSETTS

Dr. Holmes Made Professor Emeritus.—Dr. George W. Holmes, clinical professor of roentgenology, Harvard Medical School, and chief roentgenologist at Massachusetts General Hospital, Boston, will become professor emeritus, September 1, according to an announcement from the university. Dr. Holmes has been a member of the staff of Harvard since 1916 as instructor in roentgenology, 1916-1923; assistant professor, 1923-1931, and clinical professor since 1931. He has been a member of the staff of Massachusetts General Hospital since 1911 and chief roentgenologist since 1917. He was president of the American Roentgen Ray Society in 1924 and has been a director of the American Society for the Control of Cancer since 1936. He has been a member of the National Research Council since 1927. He graduated at Tufts College Medical School, Boston, in 1906.

MICHIGAN

Dr. Slemmons Returns as Health Officer of Grand Rapids.—Dr. Clyde C. Slemmons, health commissioner of Grand Rapids from 1910 to 1930, has returned to serve in this position, succeeding Dr. John L. Lavan. A native of Cedar Springs, Dr. Slemmons graduated at the Detroit College of Medicine and Surgery in 1905. He served as state health commissioner from 1930 to 1938. He was president of the International Society of Medical Health Officers in 1937. Dr. Lavan resigned to take charge of health activities in Toledo, Ohio.

Michigan Participates in Youth Health Program.—At a meeting on January 12 the council of the Michigan State Medical Society approved the program of the National Youth Administration with respect to the medical care of out-of-school youth. All young men and women of ages from 16 to 24, out of school and unemployed, may through the Michigan State Employment Service be referred to the NYA for work experience. The hours of service are sixty a month and the rate of compensation to the youth is a minimum of \$18 a month, available in work projects. As the health program is a part of the national defense movement the government is requiring a careful physical examination, utilizing a medical examination blank which will be used throughout the forty-eight states. Units of forty youths now being trained are examined each day by teams nominated by county medical societies, made up of two internists, an eye, ear, nose and throat specialist, a dentist and necessary nursing assistance. All youths are to have a Kahn test, a roentgenogram of the chest and a urinalysis for sugar and albumin. About twelve minutes is allowed every youth for each examination. With two exceptions, the defects found are, in general, referred to the family physician for correction. In the Detroit area all dental defects, positive Kahn tests and diagnosed cases of tuberculosis are referred to the Wayne County Medical Society Medico-Dental Commission or the city board of health. As the visual defects will number only five to eight on an average in this group, it was thought desirable that the specialist prescribe simple lenses for the visual correction. However, any pathologic condition that may be discovered will be referred through the family physician to the proper agency or specialist. The rate for this unit examination has been fixed at \$25 for each physician for a day's service, the hours varying from six to eight each day. In the areas where the volume of work does not warrant a unit examination the work will be done, in the main, in the private physician's office with fees varying from \$3 per examination to a proportionate part of the per diem rate. Dr. Bernard W. Carey, Detroit, health consultant to the NYA, points out that, if good medical practices are instilled into the youth now, those needing medical service when on a self-supporting basis will obtain it at the regular established fee.

MISSISSIPPI

Personal.—Dr. Clyde M. Speck, New Albany, has been appointed assistant superintendent of the Mississippi State Hospital at Whitfield, succeeding Dr. Frank A. Donaldson, who resigned to become superintendent of the East Louisiana State Hospital, Jackson.—Dr. Thomas L. Owings, health officer of Pearl River County, with offices in Poplarville, has been appointed to a similar position in Lafayette County, succeeding Dr. Murphy M. Sims, Oxford, who has gone into military service.

Regional Fracture Meeting.—Dr. Charles L. Scudder, Boston, addressed a meeting at the LaMar Hotel, Meridian, January 7, on "The Fracture Committee of Mississippi" and "The Nucleus Pulposus Backache." An executive committee has been appointed to act for the state committee in promoting plans for improving the fracture services of the hospitals, to disseminate knowledge of methods of treatment of fractures to the physicians in the state and to provide more adequately for first aid and transportation of the injured.

Public Health Election.—Dr. Richard N. Whitfield, Jackson, director of the division of vital statistics, state board of health, was chosen president-elect of the Mississippi Public Health Association at its annual meeting in Jackson, December 13. Miss Opal Regan, Meridian, was installed as president and Dr. William H. Cleveland, Tupelo, retiring president of the association, became vice president. Dr. Calvin C. Applewhite, formerly health officer of Hinds County and now with the U. S. Public Health Service, was elected an honorary member at this meeting.

NEW YORK

Personal.—Dr. Harry Beckett Lang, superintendent of the Buffalo State Hospital, has been appointed assistant commissioner of the state department of mental hygiene.—Dr. Harwood L. Hollis, Lacona, has been appointed superintendent of the Oswego County Sanatorium, Richland, to succeed his father, Dr. Leroy F. Hollis, who recently resigned after serving for twenty-two years.

Society News.—Dr. Currier McEwen, New York, discussed "Diagnosis and Treatment of Arthritis" before the Dutchess County Medical Society, Poughkeepsie, January 8. Dr. Walter D. Ludlum Jr., New York, addressed the society, December 11, on "Recognition and Treatment of Hernia."—Dr. Loring T. Swaim, Boston, addressed the Medical Society of the County of Westchester, White Plains, January 21, on the treatment of chronic arthritis.

Hospital News.—The William Henry Hall Memorial, a new \$125,000 division of the St. Agnes Hospital for crippled children, White Plains, was dedicated by Archbishop Spellman on December 15. The new building is a gift from the Hall Foundation, established in 1936 by the will of Miss Martha M. Hall, daughter of William Henry Hall, a manufacturing chemist of New York. It will accommodate forty-eight boys and is equipped with a brace shop, gymnasium, occupational therapy room, two wards, isolation room, playroom, library and physical therapy department.

New York City

Dr. George Vincent Dies.—George E. Vincent, Ph.D., former president of the Rockefeller Foundation, died in the Columbia-Presbyterian Medical Center, February 1, aged 76. Dr. Vincent was born in Rockford, Ill., March 21, 1864, and after graduating from Yale University in 1885 took the degree of doctor of philosophy at the University of Chicago in 1896. He was president of the Chautauqua Institution, Chautauqua, N. Y., from 1907 to 1915 and honorary president from 1915 to 1937. Dr. Vincent was widely known as a public speaker and lecturer. He began teaching at the University of Chicago as a fellow in sociology and remained there until 1911, when he left the position of dean of the faculties of arts, literature and science to become president of the University of Minnesota, Minneapolis. In 1917 he resigned from Minnesota to take the presidency of the Rockefeller Foundation, which he held until his retirement in 1929. He was a member of the General Education Board from 1914 to 1929.

The City's Health.—New York had record low death rates for infant and puerperal mortality, pulmonary tuberculosis, diphtheria, pneumonia and typhoid, according to the annual report of Dr. John L. Rice, commissioner of health. The number of deaths from all causes was 76,008, giving a general death rate of 10.3 per thousand of population. The infant mortality rate decreased from 37.1 in 1939 to 34.9 in 1940, and the puerperal death rate decreased in the past five years from 5.2 per thousand live births in 1935 to 3 in 1940. The rate for diphtheria was 0.7 deaths per hundred thousand children under 15 years of age. Of thirty health center districts, six had no deaths from diphtheria. The pneumonia mortality dropped from 57.6 per hundred thousand in 1939 to 46.1 in 1940. Tuberculosis caused a rate of 49, which was a decrease from 52 in 1939 and the lowest rate ever reported. Scarlet fever and measles were twice as prevalent in 1940 as in the preceding year, but there were few deaths. For whooping cough, fewer cases were reported but more deaths. The number of cases of poliomyelitis was unusually small, 67 with 5 deaths. Similarly epidemic meningitis caused fewer cases and deaths than for many years, 48 cases with 15 deaths, a result partly credited to chemotherapy. The report directs attention to appendicitis, for which the death rate declined slightly. There were, however, 677 deaths, over 7 per cent of which were in children under 5 years old. This constitutes a serious public health problem, the report points out. With the progressive aging of the city's population, chronic diseases of later life are assuming greater importance. The death rates for diabetes, cancer and diseases of the heart, arteries and kidneys and apoplexy have steadily climbed higher during the last ten years. For 1940 the rates per hundred thousand were: diabetes 42, cancer 166.3 and diseases of the heart and related conditions 473.3. The suicide rate was slightly larger than it has been in the past five years, 1,229 deaths and a rate of 16.6. The high point of recent years was a rate of 22.7 in 1932. Deaths from accidents decreased slightly, from 53.2 per hundred thousand in 1939 to 51.9 in 1940. The birth rate was 14.5 per thousand of population, the highest since 1933, when it was 14.6.

NORTH CAROLINA

Professors Appointed to Bowman Gray School.—Appointment of three new members of the faculty of the Bowman Gray School of Medicine of Wake Forest College, to open in Winston-Salem next fall, has been announced. Dr. Tinsley R. Harrison, associate professor of medicine, Vanderbilt University School of Medicine, Nashville, Tenn., has been appointed professor of medicine. Dr. Wingate M. Johnson, Winston-Salem, will be professor of clinical medicine and Dr. A. deTalma Valk, Winston-Salem, professor of clinical surgery. Dr. Harrison, a graduate of the Johns Hopkins University School of Medicine, Baltimore, in 1922, has been associated with Vanderbilt since 1925. Dr. Johnson graduated from Jefferson Medical College in 1908 and has practiced in Winston-Salem for many years. He is editor of the *North Carolina Medical Journal*. He has been on the board of trustees of Wake Forest College for twenty years and is now president of the board. Dr. Valk, a graduate from Johns Hopkins in 1910, is chief of the surgical staff of the North Carolina Baptist Hospital, Winston-Salem.

OHIO

New Society of Neurology and Psychiatry.—The Cincinnati Society of Neurology and Psychiatry was recently organized with Drs. Thomas A. Ratliff as president; Erl Armitage Baber, vice president, and Charles D. Aring, secretary. At the first scientific meeting, January 23, Dr. Aring presented a paper on "Infectious Polynucleitis."

Cleveland Health Lectures on Defense.—The annual series of free public health lectures sponsored by the Academy of Medicine of Cleveland will have as their general theme "Health in Defense." For the first session the subject will be "The Family in War Time," with Dr. William M. Champion speaking on "The Child" and Dr. Harry D. Piercy on "The Adult." Dr. George F. Sykes will give the second lecture on "The Worker in War Time," March 23, and Lieut. Col. Edgar Erskine Hume, U. S. Army Medical Corps, Carlisle Barracks, Pa., will deliver the third, April 6, on "The Soldier."

PENNSYLVANIA

Society News.—Dr. David E. Hemington, Uniontown, addressed the Fayette County Medical Society, Uniontown, February 6, on "Industrial Medicine and National Defense."—Dr. Paul Titus, Pittsburgh, addressed the Washington County Medical Society, Washington, February 12, on "Human Sterility."—Dr. William F. Petersen, Chicago, was the guest speaker at the annual combined meeting of the McKeesport Academy of Medicine and the Valley Medical Society in McKeesport, January 27, on "Weather and the Practice of Medicine."

Philadelphia

Medicolegal Night.—The Philadelphia County Medical Society devoted its February 12 meeting to "The Crime Problem—New Concepts and Contributions." The speakers were William Draper Lewis, Ph.D., director of the American Law Institute, on "The American Law Institute's Youth Correction Authority Act" and Dr. Foster Kennedy, New York, "The Psychiatrist's Responsibility to the Criminally Insane and to Society." Commentators were the Hon. James Gay Gordon Jr., president-judge, common pleas court No. 2, and Dr. Edward A. Strecker. Members of the judiciary and the bar association were guests at the meeting.

Pittsburgh

Personal.—Homer Saint-Gaudens, for the last twenty years director of fine arts at Carnegie Institute in Pittsburgh, is now on active duty in the Corps of Engineers and as technical advisor on camouflage studies being conducted in the office of the Chief of Engineers in Washington, D. C. Colonel Saint-Gaudens is the son of Augustus Saint-Gaudens, the great Irish-American sculptor; he served in the first World War with the first camouflage unit and was in charge of camouflage on the front of the second camouflage division.

Society News.—Speakers at a meeting of the Pittsburgh Surgical Society, January 24, were Drs. Edward J. McCague on "Traumatic Injuries of the Genito-Urinary Tract"; Grover C. Weil, Harold W. Rusbridge and Darrell W. Whitaker, "Treatment of Compound Wounds and Surgical Infections by the Local Implantations of Sulfathiazole, with Special Reference to Compound Fractures," and Stuart N. Rowe, "Neurosurgical Treatment of Certain Types of Low Back Pain."

TENNESSEE

Plans for Psychiatric Hospital.—Plans for a diagnostic clinic and psychiatric hospital as an addition to the John Gaston Hospital, Memphis, teaching hospital of the University of Tennessee College of Medicine, have been announced. The new building will have six floors, four to be used as an outpatient department for the John Gaston Hospital and two for a fifty bed psychiatric hospital. It will cost about \$450,000. All patients admitted to the Western State Hospital, Bolivar, will enter the psychiatric hospital for diagnosis and classification, and selected cases will be kept there for treatment for instructional purposes. Medical students will be rotated through the psychiatric hospital as in other departments.

TEXAS

Special Society Meeting.—Dr. Everett L. Goar, Houston, was elected president of the Texas Ophthalmological and Otolaryngological Society at its annual meeting in Fort Worth in December. Drs. Burbank P. Woodson, Temple, and Phocian W. Malone, Big Spring, were elected vice presidents and Dr. Daniel Brannin, Dallas, was reelected secretary. The guest speakers were Drs. Samuel J. Kopetzky, New York, on management of otitis and Peter C. Kronfeld, Chicago, early diagnosis of glaucoma.

Clinical Assembly in San Antonio.—The International Postgraduate Medical Assembly of South Texas held its ninth annual clinical meeting in San Antonio, January 28-30. The lecturers were Drs. Horton R. Casparis and Tinsley R. Harrison, Nashville, Tenn.; William H. Crisp and Franklin G. Ebaugh, Denver; Temple S. Fay, Philadelphia; Walter A. Fansler, Minneapolis; Bernard H. Nichols and Roy W. Scott, Cleveland; Francisco de P. Miranda, Mexico City; Thomas B. Sellers, New Orleans; John A. C. Colston, Baltimore; Roy D. McClure, Detroit; John R. Page and Arthur Purdy Stout, New York; Francis M. Rackemann, Boston; John C. Wilson, Los Angeles, and Major Samuel F. Seeley, Fort Sam Houston, Texas.

UTAH

Society News.—The Carbon County Medical Society was addressed in Price City, December 11, by Dr. Thomas F. Welsh, Salt Lake City, on "Otitis Media, Complications and Treatment."

VIRGINIA

Annual Course in Ophthalmology and Otolaryngology.—The fifteenth annual spring graduate course will be presented by the Gill Memorial Eye, Ear and Throat Hospital, Roanoke, April 7-12. Guests who will conduct clinics include Drs. Alfred Cowan and Robert A. Groff, Philadelphia; James H. Maxwell, Ann Arbor, Mich.; Paul M. Moore Jr. and Albert D. Ruedemann, Cleveland; Raymond E. Meek, Algonon B. Reese, Clarence R. Straatsma and Arno E. Town, New York; Carleton Stewart Nash, Rochester, N. Y.; Leroy A. Schall and Theodore L. Terry, Boston; Warren T. Vaughan, Richmond, and Frank B. Walsh, Baltimore.

Society News.—Dr. Bayard T. Horton, Rochester, Minn., addressed the Neuropsychiatric Society of Virginia at a meeting in Charlottesville recently on "A New Syndrome of Vascular Headache: Results of Treatment with Histamine." Speakers at a meeting of the Fourth District and Southside Virginia Medical Society in Petersburg, December 27, included Drs. Ramsay Spillman, New York, on "What Every Physician Should Know About the Spread and Prevention of Tuberculosis"; Thomas Duckett Jones, Boston, "New and Interesting Phases of Rheumatic Fever"; William B. McIlwaine III, Petersburg, "Sulfathiazole and Allied Types of Chemotherapy in Children," and Claude C. Coleman, Richmond, "Signs and Symptoms of Brain Tumors That Should be Familiar to Every Physician."—The Roanoke Academy of Medicine held a special meeting February 3 with Drs. Herbert F. Traut, New York, and Joseph Earle Moore, Baltimore, as the speakers on "Upper Urinary Tract Infection Complicating Pregnancy" and "Venereal Disease Control in the Armed Forces" respectively.

WISCONSIN

Lakeside Laboratories Expand.—Drs. Elmer L. Sevringhaus, Madison, and Eugene F. Traut, Chicago, were the speakers at a meeting on December 28 marking the opening of a new building of the Lakeside Laboratories, Milwaukee. Dr. Sevringhaus discussed "Clinical Endocrinology" and Dr. Traut "Treatment of Arthritis." The new addition doubles the space previously occupied by the firm.

Lippitt Memorial Lecture.—Dr. Lee E. Farr, director of research, DuPont Institute, Wilmington, Del., delivered the sixth annual Lippitt Memorial Lecture, January 17, at the Marquette University School of Medicine, Milwaukee. His subject was "The Role of Diet in the Therapy of Nephritis." The lecture honors the late Dr. S. Herman Lippitt, associate clinical professor of pediatrics at the university for many years before his death in 1934 and for ten years on the staff of Mount Sinai Hospital.

GENERAL

Grants Available for Infantile Paralysis Research.—The National Foundation for Infantile Paralysis will hold a semiannual meeting of its medical committees on May 15 to consider grants for study of the cause, prevention and treatment of infantile paralysis. Applications must be received on or before March 15 at the office of the foundation, 120 Broadway, New York.

American Diabetes Association.—A new organization known as the American Diabetes Association, Inc., has been formed, and committees are now at work on membership and program. The officers of the new organization are Drs. Cecil Striker, Cincinnati, president; Herman O. Mosenthal, New York, and Joseph T. Beardwood Jr., Philadelphia, vice presidents; Samuel S. Altschuler, Detroit, secretary; William Muhlberg, Cincinnati, treasurer. The honorary president is Dr. Elliott P. Joslin, Boston, and the honorary members are Drs. Frederick G. Banting and Charles H. Best, Toronto. The board of trustees comprises thirteen well known physicians from various cities.

"Pan American Union Against Cancer" Not Known.—The Pan American Sanitary Bureau recently issued the following statement: "It has come to the notice of the Pan American Sanitary Bureau that some one (not a physician) has been trying to organize a Pan American Union Against Cancer. An inquiry has elicited from Dr. Ludvig Hektoen, executive director of the National Advisory Cancer Council of the United States, the information that the National Cancer Institute is not in any way associated with this project and that no other governmental agency is supporting it to date, nor, so far as is known, is the American Society for the Control of Cancer."

Legislation for Control of Fireworks.—The National Fire Protection Association Model State Fireworks Law has been introduced in the following states:

Kansas: House bill 65, referred to Committee on State Affairs.
Minnesota: House bill 47, referred to General Legislative Committee.
Massachusetts: House bill 1651, referred to Committee on Military Affairs and Public Safety.
Ohio: House bill 12.
North Carolina: A senate bill, referred to Committee on Propositions and Grievances. (This bill was introduced by Senator D. M. Stringfield.)
Maryland: House bill 29, referred to Judiciary Committee.

This legislation is planned to control unnecessary hazard to health and property from the use of fireworks under uncontrolled conditions.

Orthopsychiatric Meeting.—The American Orthopsychiatric Association will hold its eighteenth annual meeting at the Hotel Pennsylvania, New York, February 20-23, under the presidency of Dr. Paul L. Schroeder, Chicago. The program will open with a symposium on "What Can Psychiatry Contribute to the Alleviation of National and International Difficulties?" A luncheon round table on pediatrics and child psychiatry will follow. There will be another symposium on "Direct Psychotherapy in Adolescence" and special sessions devoted to cultural psychology, psychopathology of childhood and youth, therapy, case work and the case worker, education and school, family and foster home and prevention. Dr. Schroeder will deliver his presidential address at the annual dinner on Friday evening.

Special Society Elections.—Dr. Carl E. Badgley, Ann Arbor, Mich., was chosen president-elect of the American Academy of Orthopaedic Surgeons at its annual meeting in New Orleans, January 16, and Dr. Oscar L. Miller, Charlotte, N. C., was inducted into the presidency. Other officers are Drs. Herman C. Schumm, Milwaukee, vice president; Eugene Bishop Mumford, Indianapolis, treasurer, reelected, and Rexford L. Diveley, Kansas City, Mo., secretary.—Dr. Ernest W. Goodpasture, Nashville, Tenn., was elected a vice president of the American Association for the Advancement of Science and chairman of the section on medical sciences (N) at the annual midwinter meeting in Philadelphia.—Dr. Oswald T. Avery, New York, was elected president of the Society of American Bacteriologists at the annual meeting in St. Louis in December.

Fellowships in Child Psychiatry.—The National Committee for Mental Hygiene announces that a limited number of fellowships for training in extramural psychiatry, especially child psychiatry, have been provided by the Commonwealth Fund and other sources. Fellows are to be assigned through the committee for one or two years to a selected child guidance clinic, the term and plan of the fellowship to be determined by the peculiar needs of the fellows. Candidates for fellowship awards should have at least two years of psychiatry in an approved mental hospital, in addition to other qualities fitting them for extramural service. Other conditions such as age, sex and marital status will be governed by individual cases and by the nature of the demand. Requests for applications for fellowships should be addressed to Dr. Milton E. Kirkpatrick, National Committee for Mental Hygiene, Room 916, 1790 Broadway, New York.

Examinations by Obstetric Board.—General oral and pathological examinations (part II) for all candidates (groups A and B) will be conducted by the American Board of Obstetrics and Gynecology at Cleveland May 28 to June 2, inclusive. Application for admission to group A, part II, examinations must be on file in the office of the secretary not later than March 1. Candidates for reexamination in part II must make written application to the secretary's office before April 15. The board states that military service will not affect the eligibility of any candidate as far as the board requirements regarding limitation of practice are concerned. Military service will under no circumstances be considered as an infringement of any regulations outlined in this board's booklet. The board requests that all candidates who plan to submit applications use the new form, which may be obtained from the secretary on request. Address Dr. Paul Titus, Secretary, 1015 Highland Building, Pittsburgh (6).

American Physicians' Art Association.—The secretary of the American Physicians' Art Association, Dr. Francis H. Redewill, 521 Flood Building, San Francisco, requests any physician who has an art piece in any medium that he would like to donate as a trophy to the American Physicians' Art Association to send it properly boxed and shipped express collect to the librarian H. G. Marquez, Ph.D., American Physicians' Art Association, 521 Flood Building, San Francisco. Art pieces donated will be placed on exhibition in the booth of the association in Cleveland, June 2-6, during the annual session of the American Medical Association. Dr. Redewill has sent to members of the American Physicians' Art Association a questionnaire asking for brief information about each member which the association will publish in booklet form; snapshots and other pictures of members at work or play also are requested. The headquarters of the American Physicians' Art Association at the Cleveland meeting will be booth 493 in the technical exhibit of the American Medical Association, a booth which Mead Johnson & Co. has offered the art association.

Pacific Coast Surgical Association.—The sixteenth annual meeting of the Pacific Coast Surgical Association will be held at the Ambassador Hotel, Los Angeles, February 19 under the presidency of Dr. Charles T. Sturgeon, Los Angeles, whose subject will be "The Surgical Management of Chronic Duodenal Ulcer." Other speakers will be:

- Dr. Henry H. Searls, San Francisco, A Family with Hemolytic Icterus.
- Dr. William K. Livingston, Portland, Ore., Back Disabilities Due to Strain of the Multifidus Muscle Treated by Novocain Injections.
- Drs. Leroy C. Abbott, John B. de C. M. Saunders and Carl E. Anderson, San Francisco, Injuries to the Ligaments of the Knee.
- Dr. Thomas F. Mullen, San Francisco, The Urologic Complications of Carcinoma of the Rectum.
- Dr. George K. Rhodes, San Francisco, Observations on Acute Pancreatitis with Blood Amylase Studies.
- Dr. John Homer Woolsey, Woodland, Calif., The Problem of the Common Duct Stone.
- Dr. Robert D. Forbes, Seattle, Secondary Operations on the Biliary System.
- Dr. Emil F. Holman, San Francisco, Aseptic Technique for Resection of the Stomach.
- Drs. Samuel Robinson and Leigh Gordon Fiske, Santa Barbara, Calif., An Instrument for Retraction of Viscera During Peritoneoscopy.
- Dr. Brian T. King, Seattle, Further Observations on an Operation for the Relief of Bilateral Abductor Cord Paralysis.
- Dr. Herbert S. Chapman, Stockton, Calif., Hyperparathyroidism.
- Dr. Raymond E. Watkins, Portland, Ore., Carcinoma of the Cervical Stump Following Hysterectomy.
- Dr. Ous F. Lamson, Seattle, An Appliance for Colostomy Control.

College of Physicians Offers Postgraduate Courses.—For the fourth year the American College of Physicians has arranged a series of postgraduate courses in cooperation with various institutions. The courses vary in length from one to three weeks and are offered primarily for fellows and associates of the college, but where facilities are available they

are open to physicians preparing either to meet the requirements for membership in the college or for the examinations of the American Board of Internal Medicine. During February courses are being given as follows: allergy, Washington University School of Medicine, St. Louis, under the direction of Dr. Harry L. Alexander; allergy, Roosevelt Hospital, New York, under Dr. Robert A. Cooke, and gastrointestinal diseases, Mayo Foundation and Mayo Clinic, Rochester, Minn., under Dr. Edgar V. Allen. Future courses are announced as follows:

- General medicine, Harvard Medical School, Boston, March 31 to April 18, under Drs. James H. Means, George R. Minot, Soma Weiss and Robert T. Monroe.
- Allergy, Massachusetts General Hospital, Boston, April 10-18, under Dr. Francis M. Rackemann.
- Gastroenterology, Robert Dawson Evans Memorial, Massachusetts Memorial Hospitals, Boston University, April 14-19, under Dr. Chester S. Keefer.
- General medicine, University of Michigan Medical School and University Hospital, Ann Arbor, April 7-19, under Dr. Cyrus C. Sturgis.
- Clinical medicine from the hematologic point of view, Ohio State University College of Medicine, Columbus, April 14-19, under Dr. Charles A. Doan.
- Cardiovascular disease, University of Pennsylvania School of Medicine and Graduate School of Medicine, Philadelphia, April 7-19, under Dr. William D. Stroud.
- Military medicine, U. S. Army Medical Corps, U. S. Navy Medical Corps and U. S. Public Health Service, Washington, D. C., April 7-18, with Dr. Wallace M. Yater as coordinator.

CORRECTIONS

Anorectal Operative Procedures with Special Reference to Avoidance of Pain.—In THE JOURNAL, February 1, page 363, in the discussion of Dr. Arthur S. Calman on the paper by Dr. Harry E. Bacon, two sentences were inadvertently omitted. After the sentence "A suture ligature of number 00 plain catgut, which is absorbed shortly, is then passed around the distal end of the hemorrhoid and ligated" the following two sentences should follow: "The hemorrhoidal mass, composed of vein and periphrigebic areolar tissue, is then dissected out from its bed without sacrificing any mucosa. The two mucosal flaps covering the operative area are not sutured together."

National Emergency and Health Insurance.—In the editorial entitled "The National Emergency as a Pretext for Compulsory Health Insurance" in THE JOURNAL, January 25, there is in the first sentence of the last paragraph on page 310 an erroneous statement with respect to the number of initiative measures that were before the Washington electorate in the November election. Only three such measures were on the ballot and not "a hundred or more," as stated in the editorial. However, the further statements made in discussing initiative measure 141, the so-called Senior Citizens Grants Act, which was approved by the Washington electorate, are correct. The measure does require the state to provide at the expense of the state medical, hospital, dental and nursing care to persons eligible for the senior citizen grants authorized by the measure. And the ballot title of the measure did not indicate to the voter that he was passing on a measure that would provide medical care at the expense of the state to the beneficiaries of the measure.

Government Services

Physicians Needed for CCC Duty

Applications are invited from physicians for medical service in the Civilian Conservation Corps in the Seventh Corps Area, which includes Minnesota, North and South Dakota, Iowa, Nebraska, Missouri, Kansas and Arkansas. The initial salary is \$3,200 a year. No quarters for families are provided, and the physicians are required to pay for their own food at the camps. The principal duties consist of the medical care of the enrollees and the practice of preventive medicine. To be eligible for this service, the physician must be a citizen of the United States, a graduate of an accredited medical school authorized to confer the degree of doctor of medicine and physically able to perform the duties involved. All physicians interested in this type of work are requested to submit their applications to the Office of the Surgeon, Seventh Corps Area, Federal Building, Omaha.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Dec. 28, 1940.

The Food Situation in Europe

In a previous letter it was shown that the food shortage in Europe, apart from that due to the ravages of war, was the result of plundering of the enslaved peoples by the Germans. Britain's contention that there is no necessity for America to send food ships to German occupied countries, as advocated by Mr. Hoover and others, is confirmed by a report issued by the Berlin Institute for Business Research. This claims that Germany is in a position to guarantee the feeding of every one on the Continent and says that, since exports to England have ceased, foodstuffs produced in Europe provide nourishment for the peoples under the German distribution organization. A list attached to the report gives German stocks and production as 90 per cent of the requirements, southeastern Europe as 110 and other percentages as Denmark 108, Italy 95, France 83, the Netherlands 67 and Belgium 51. No figures are given for Poland or Norway. But reliable reports have reached the British Ministry of Economic Warfare that two million workers brought into Germany from occupied countries are finding their food rations inadequate and that bad feeding has led to disturbances. Referring to Mr. Hoover's efforts in the last war to relieve the food shortage in Germany, Mr. Hugh Dalton, minister of economic warfare, said in a speech "I am afraid that they prolonged the war and cost the lives of many, including American soldiers." He could not see the arguments for Mr. Hoover's latest plan. There was no reason to suppose that there would be any starvation on the Continent unless the Germans willed it. If we did let in food, it would inevitably assist the enemy.

There are signs that the food position in France may become tragic. The Germans have seized about 60 per cent of all the crops in both occupied and unoccupied France. They have taken the pigs and all other supplies of animal fat. The weekly meat ration of 13 ounces includes bones and trimmings, leaving only about 10 ounces of actual meat. To obtain this quantity it is necessary in certain cities to form queues as early as 4 a. m. In the cities there is no butter or suet. Soap is almost unobtainable. Stocks of fruit are rapidly coming to an end; as much as 25 cents is sometimes paid for an apple. The Germans have removed from Normandy and Brittany all the cider apples for the manufacture of some war product of which the nature is not known. The restaurants serve food against ration cards, but the amount is inadequate. German officers eating in restaurants are given the ration cards for three persons and other ranks the cards for two.

The British government has given the International Red Cross Committee at Geneva an assurance that ships carrying parcels for prisoners of war and containing foodstuffs, blankets and underclothing, will be allowed to proceed freely to Europe. The parcels are to be unshipped at Lisbon and transported and distributed by the Red Cross. The British government has also declared itself ready to facilitate the importation into European countries of strictly medical and pharmaceutical products intended for the sick and wounded.

The Danger of Flying Glass in Air Raids

The research and experiments department of the Ministry of Home Security has shown that the danger during air raids from flying glass is considerable. While the fragments have not caused many deaths, they have been responsible for a large proportion of the injuries when the bombs have fallen among houses and also for serious damage to food stocks. The blast of a bomb falling within 200 feet may burst windows and cause

a hail of broken glass, driving dagger-like pieces into walls or into cans containing food. Curtains and blinds do little to stop flying glass. Materials pasted on glass have proved effective in preventing glass fragments from flying, though they do not prevent windows from being broken. The cheapest and simplest material to use is cotton or linen fabric pasted all over the glass with paperhanger's paste. Brown paper will do if tough and thick. Windows left open are less likely to suffer from the effects of a blast.

Science and War

In a broadcast Sir William Bragg, lately president of the Royal Society, took for his subject Science and War. He said that the war had been called a scientists' and engineers' war. When people saw the damage it was natural for them to curse scientists and engineers for their devilish inventions. But science was knowledge about the world around us, which scientists were trying to increase. They could not control the use made of inventions. The same knowledge might be used to make drugs which controlled a deadly disease or to make poison gas. We lived in an age in which machines of all kinds were improved rapidly from year to year and the same held for weapons of war.

When war threatened, the Royal Society made a register of our scientists—an action never taken before. The results were interesting. We had about ten thousand scientific researchers, of whom sixteen hundred were chemists, one thousand physicists, five hundred mathematicians and seven hundred zoologists. Fifteen hundred were engaged in medical research. The remaining three or four thousand scientists were employed in the universities and technical colleges. Our trouble was that we had not organized our scientists for war. Apart from a small band in service departments, our scientists were engaged in peaceful occupations, whereas the best German technicians had been drawn in for many years. But fortunately the British were good at improvising in an emergency. He could not give away any secrets, but he could quote from a German source. In his book, Captain Dove, one of the prisoners on the *Graf Spee*, related what Captain Langsdorf of that ship said "We invented the magnetic mine eight years ago and for eight years have been trying to find the antidote without success. Now the British Navy has to start where we began." But the British Navy found the antidote in eight weeks, not eight years.

Sir Arthur Hurst

Sir Arthur Hurst has retired from the active staff of Guy's Hospital, where his great pioneer work in medicine has been done, although his personal teaching will continue in another but related sphere. Owing to the difficulty in carrying out clinical teaching in the London hospitals during the war, it was decided last October to start a clinical school in Oxford for students who, having finished their preclinical course, would under ordinary conditions have gone to London hospitals for their clinical work. Nearly all the students have availed themselves of the opportunity of doing their clinical work in comparatively peaceful surroundings. Sir Arthur Hurst and Prof. George Gask, formerly director of the surgical unit at St. Bartholomew's Hospital, were invited to help the medical and surgical staffs of the Radcliffe Infirmary, Oxford, in their clinical teaching and have been appointed respectively lecturer in clinical medicine and lecturer in clinical surgery of the University of Oxford.

Sir Arthur Hurst has also retired from the editorship of *Guy's Hospital Reports*, and the current number is dedicated to him in commemoration of his work, which is described as follows: "The origin, continuance and great success of the quarterly series during nineteen years have been entirely due to his energy, inspiration and unremitting labor. Between the two European wars they have been a manifestation of Hurst himself." To the *Reports* he has contributed seventy-eight

papers, of which sixty-four appeared during his editorship. Many, such as "The Passage of Food Along the Alimentary Canal," "The Sensibility of the Alimentary Canal" and "The War Neuroses and the Neuroses of Civil Life," have become classic, and all of them have proved valuable and stood the test of time—characteristics of Hurst's work.

He has been not only a great contributor to the *Reports* but an inspiring teacher, leader and editor. Hurst's influence also extends to sixty-one papers written by members of the hospital staff, such as registrars, house physicians and clinical assistants. A feature of Guy's Hospital, perhaps unique in the medical world, is two clinical wards to which cases of special interest are admitted and which is always a center of active research. The appointment as clinical assistant to these wards is one of the oldest nonsurgical clinical appointments in the world and certainly goes back one hundred years. Every three months, six senior students are appointed to these wards. Most of the cases quoted by Bright and Addison in their classic works were written by "clinicals." As these two famous Guy's physicians have been mentioned, a third, Hodgkins, may be added, as all three have passed into history in eponyms. A valuable feature of the present series of the *Reports* is seven yearly publications of "Cases from Clinical." It was in 1836 that *Guy's Hospital Reports* first appeared as a yearly volume, and it was continued until 1915, when publication was suspended by the great war, to be resumed in 1921 as a quarterly under the editorship of Sir Arthur Hurst. Perhaps at no hospital in the world has so much been done to increase clinical knowledge, and no other reports contain so much valuable material.

PALESTINE

(From a Special Correspondent)

Nov. 16, 1940.

Twenty Years of British Medical Service in Palestine

Col. G. W. Heron, director of medical services, spoke on the radio on twenty years' medical service of the British administration in Palestine. Under the Turks, which means before 1917, there was no organized medical service in the country. Some medical officers in larger towns performed sanitary and medical work. Hospitals existed only in Jerusalem and Nablus. After the occupation in 1917 a public health section under the late Colonel Garner was established. In 1920 the military administration was replaced by a civil government. The department of health was created. Colonel Heron stated that progress has not been confined to the activities of the government. Each community has had a share: the Mission hospitals, the Jews with the Hadassah and Kupath Cholim organization, the Arabs and Moslems with voluntary hospitals and free clinics. In 1920 there were twenty-three public hospitals. In 1940 there are thirty-nine. The Jewish community maintains today twelve, the government nine, the Arabs one purely Arab voluntary hospital. The most modern and largest hospitals are the Government Hospital at Haifa and the Hadassah University Hospital, built in 1939, on Mount Scopus, Jerusalem.

In 1918, before hostilities in Palestine ceased, the American Zionist Medical Unit came to Palestine and formed the nucleus of the Jewish medical service of today. This service included the Hadassah organization with its hospitals, school and infant welfare services; the Kupath Cholim organization, with over a hundred thousand members, some municipal or community hospitals, the antituberculosis league, the organization for the crippled children and other welfare services. Colonel Heron told about the antimalarial work. "In the last war Lord Allenby had to reckon on 5 to 10 per cent of his fighting forces being noneffectives from this cause between April and October 1918. Today among the men under General Neame that figure stands at a fraction of 1 per cent."

There are eighty-five babies' welfare centers, forty-eight supported by the Jewish community, thirty-four by the government and three by mixed Arab and European woman's committees. The general infant death rate in Palestine has been reduced to less than half what it was in 1920. With the assistance of Sir John Strathearn and his collaborators a government service has been established throughout the country with thirty-one eye clinics, of which twenty are first aid stations in villages. This service includes a mobile unit with a specially fitted lorry, a trailer caravan for the nurses and tents; 32,000 patients have been treated till now in tents. Colonel Heron's report included the work on hookworm, tuberculosis and quarantine control, the collaboration with laboratories and sanitary surveyors of municipalities and ambulance service.

Venereal Disease Control

A control scheme for fighting venereal diseases in Palestine was established four years ago. Now a review in *Health and Empire* notes the rapid strides made against these diseases. The total number of attendances at various clinics amounted to 9,729 in 1936 and 42,730 in 1939. For seamen of all nationalities exist facilities for free treatment in Haifa and Jaffa. A special campaign was made against endemic syphilis in Hebron, where the infection was commonly acquired by infants from neglect of hygienic conditions.

Australian Gift to the Red Cross

During September nine all steel motor ambulances built by Jewish and Arab factories in Palestine were delivered to Lord Somers, Middle East commissioner for the British Red Cross, by Col. Harold Cohen, overseas commissioner for the Australian Red Cross Society. Lieut. Gen. Sir Thomas Blamey accepted three weeks ago six motor ambulances for the Australian Imperial Force as a gift of the Australian Red Cross.

Appointment of Prof. Chaim Weizman

Prof. Chaim Weizman, president of the Jewish Agency and director of the Daniel Sieff Research Institute at Rehovot, has been appointed a scientific adviser to the British government, and a government laboratory has been put at his disposal. In 1914 Professor Weizman was lecturer in chemistry at Manchester University and discovered a valuable method of synthesizing acetone. This method permitted him to make acetone out of horse chestnuts.

Cancer Research Institute

The new department of the medical school (Nathan Ratnoff building) of the Hebrew University is the Cancer Research Institute under the direction of Professor Halberstaedter and Dr. Doljanski. Prof. Carl Neuberg has been appointed director of the chemical department of the Cancer Research Institute. Professor Neuberg was director of the Kaiser-Wilhelm Institute of Biochemistry in Berlin-Dahlem, and was founder and editor of the *Biochemische Zeitschrift*.

Marriages

WILLIAM MORTON BOGART JR., Minneapolis, to Miss Bertha Mae Johnson of Clifton Forge, Va., Nov. 9, 1940.

FREDERICK A. DOWDY, Birmingham, Ala., to Miss Anne M. Elliott of Moundville in Cleveland, Nov. 4, 1940.

FRANCIS NICHOLSON TAYLOR to Miss Sarah Elizabeth Madison, both of Petersburg, Va., Nov. 12, 1940.

THOMAS GIBSON BROOKS, Aiken, S. C., to Miss Alice Danforth in New York, Nov. 16, 1940.

THOMAS A. COATES, Youngstown, Ohio, to Miss Virginia O'Hearn at St. Louis, Nov. 1, 1940.

BERNARD S. ANDROSKY, Pittston, Pa., to Miss Marie Austin of Exeter, Nov. 16, 1940.

Deaths

Charles Wardell Stiles * Medical Director, United States Public Health Service, Washington, D. C., who retired from active duty, Oct. 1, 1931, died, January 24, in the U. S. Marine Hospital, Baltimore, of myocarditis. Dr. Stiles was born in Spring Valley, N. Y., May 15, 1867. He received his early education at Wesleyan University, Middletown, Conn., and studied later at foreign universities, taking the degree of doctor of philosophy at Leipzig in 1890. He was awarded the honorary M.D. degree from the University College of Virginia, Richmond, in 1913. Dr. Stiles began his service with the government in 1891 as zoologist to the bureau of animal industry of the department of agriculture. In 1902 he joined the public health service as professor of zoology. He held teaching positions in medical zoology at Georgetown University from 1892 to 1906, the Army Medical School from 1894 to 1902, Johns Hopkins University from 1897 to 1937 and the Naval Medical School from 1905 to 1910. From 1909 to 1914 he was scientific secretary of the Rockefeller commission for the eradication of hookworm. He was the author of many books relating to his specialty and of a key catalogue of the parasites of man and animals, indexed in all the most important languages. Dr. Stiles was honorary custodian of the helminthological collections in the United States National Museum from 1893 to 1931; secretary of the advisory commission of the Smithsonian Table at Naples Zoological Station since 1894; United States government delegate to the International zoological congresses in Leiden in 1895, Cambridge 1898, Berlin 1901, Berne 1904, Boston 1907, Graz 1910, Monaco 1913, Budapest 1927 and Padua 1930. He was secretary of the International Commission on Zoological Nomenclature from 1897 to 1936 and secretary of the International Commission on Medical Zoology from 1910 to 1913. He was detailed as agricultural and scientific attaché in the United States Embassy, Berlin, Germany, 1898-1899. Since 1931 he had been an associate of the Smithsonian Institution, professor of zoology at the Rollins College, Winter Park, Fla., from 1931 to 1938 and a member of many American and European scientific societies. In 1892 he was elected foreign correspondent of the Société de biologie, France; in 1896 foreign correspondent of the Académie de médecine, France, and in 1899 corresponding member of the Zoological Society of London.

William Browning * Brooklyn; Universität Leipzig Medizinische Fakultät, Saxony, Germany, 1881; lecturer on anatomy and physiology of the nervous system from 1884 to 1901, professor of neurology from 1901 to 1926 and since 1926 emeritus professor of neurology at the Long Island College Hospital, now the Long Island College of Medicine; president, 1901, and trustee since 1927, Medical Society of the County of Kings; a founder and past president of the Medical Library Association and of the Brooklyn Neurological Society; member of the American Neurological Association and the Association of American Anatomists; for many years state examiner in lunacy; served on the staffs of the Kings County, Wyckoff Heights, Long Island College, Jewish, Norwegian, St. John's, St. Catherine's, St. Christopher's, Brooklyn, Brooklyn State, Bushwick, Long Island State, Caledonian, Eastern District and Sea View hospitals; author of "The Normal and Pathological Circulation in the Central Nervous System" and "Medical Heredity"; aged 85; died, January 5, of carcinoma of the rectum.

George Frederick Juenemann * Colonel, United States Army, retired, Los Angeles; Columbian University Medical Department, Washington, D. C., 1897; entered the army as an assistant surgeon Sept. 12, 1903; veteran of the Spanish-American and World wars; retired as a lieutenant colonel Dec. 31, 1922, for disability in line of duty; was retired as a colonel by a special act of Congress June 21, 1930; aged 65; died, Dec. 10, 1940, in the Veterans Administration Facility, West Los Angeles, of coronary occlusion.

Henry Bernard Freiberg * Cincinnati; University of Cincinnati College of Medicine, 1918; assistant professor of clinical surgery (urology) at his alma mater; member of the American Urological Association; formerly secretary of the Cincinnati Academy of Medicine; fellow of the American College of Surgeons; attending urologist, Children's, Cincinnati General and Jewish hospitals; director, urology division, Deaconess Hospital; assistant attending urologist, Christ Hospital; aged 46; died, January 22, of pulmonary thrombosis and abscess due to a fall.

Charles Stewart Barnes, Philadelphia; Jefferson Medical College of Philadelphia, 1897; member of the Medical Society of the State of Pennsylvania; associate professor of obstetrics, Temple University School of Medicine; past president of the Philadelphia Obstetrical Society; aged 78; on the staff of the Philadelphia General Hospital; for many years on the staff of the Temple University Hospital, where he died, Dec. 29, 1940, of carcinoma of the stomach with metastasis.

Clyde Ernest Stackhouse * Bismarck, N. D.; Northwestern University Medical School, Chicago, 1910; was a delegate of the American Medical Association at a special session in 1935; past president of the North Dakota State Medical Association; formerly medical referee of the North Dakota State Board of Public Welfare; on the staff of St. Alexius Hospital; aged 55; died, Dec. 26, 1940, of coronary thrombosis.

John Howard Allen * Colonel, United States Army, retired, Dixon Springs, Tenn.; Columbian University Medical Department, Washington, D. C., 1899; entered the army as an assistant surgeon July 16, 1901; veteran of the Spanish-American and World wars; promoted through the various grades to that of colonel, June 29, 1927; retired Feb. 28, 1934, for disability in line of duty; aged 67; died, Dec. 3, 1940, of pneumonia.

Thomas Reese Foster, Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891; served during the World War; on the staff of the Leland Sanatorium, Ypsilanti, Mich.; aged 72; died, Dec. 3, 1940, in the Veterans Administration Facility, Hines, of gastric carcinoma.

Bernard Patrick Murphy, Putnam, Conn.; Jefferson Medical College of Philadelphia, 1895; member of the Connecticut State Medical Society; veteran of the Spanish-American War; aged 68; on the staff of the Day Kimball Hospital, where he died, Dec. 14, 1940, of carcinoma of the cecum.

Francis Parrier Horan * Evanston, Ill.; University of Pennsylvania Department of Medicine, Philadelphia, 1907; served during the World War; on the staff of St. Francis Hospital; aged 60; died, Dec. 23, 1940, of coronary thrombosis.

Zera Merritt Beaman * North Manchester, Ind.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; past president of the Wabash County Medical Society; aged 60; died, Dec. 20, 1940, of cerebral hemorrhage.

Marion Donoby Eubank, Kansas City, Mo.; Marion-Sims College of Medicine, St. Louis, 1893; Northwestern University Medical School, Chicago, 1896; formerly a medical missionary; aged 78; died, Dec. 5, 1940, of cerebral hemorrhage.

George Nelson Murphy, St. Johns, Newfoundland; Halifax Medical College, Halifax, N. S., Canada, 1895; Bellevue Hospital Medical College, 1895; past president of the Newfoundland Medical Society; aged 70; died, Nov. 18, 1940.

Horace E. Evans, Perry, Ga.; Atlanta School of Medicine, 1911; member of the Medical Association of Georgia; aged 56; was killed, Dec. 15, 1940, when the automobile in which he was driving was struck by a train.

William Fuller Conners, Fulton, N. Y.; University of the City of New York Medical Department, 1880; aged 90; died, Nov. 14, 1940, of chronic nephritis and myocarditis.

Leroy Bromwell Humphrey, Los Angeles; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1893; aged 73; died, Dec. 15, 1940, of coronary occlusion.

Luke Irdel Foster, Ellijay, Ga.; Boston University School of Medicine, 1933; member of the Medical Association of Georgia; aged 32; died, Dec. 10, 1940, of heart disease.

Stephen Don Dorsey, Cumberland, Iowa; State University of Iowa College of Medicine, Iowa City, 1937; aged 27; was found dead, Dec. 2, 1940, of a self-inflicted bullet wound.

Francis Asbury Appgar, Oldwick, N. J.; Bellevue Hospital Medical College, New York, 1876; aged 89; died, Dec. 30, 1940, of uremia, pyelonephritis and posterior spinal sclerosis.

John Harbour McBee, Greenwood, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1903; aged 57; died, Dec. 14, 1940, of coronary thrombosis.

Justin Angus McDonald, Prince Albert, Sask., Canada; University of Manitoba Faculty of Medicine, Winnipeg, 1926; aged 41; died, Nov. 6, 1940.

Cyrus E. Johnston, Anna, Ohio; Starling Medical College, Columbus, 1880; aged 90; died, Dec. 19, 1940, of heart disease.

John F. Jessee, Waddy, Ky.; Louisville Medical College, 1888; aged 82; died, Dec. 7, 1940, of cardiac thrombosis.

Ralph Van Carpenter, Denver; Rush Medical College, Chicago, 1927; aged 42; died, Dec. 13, 1940.

PREGNANCY ACCIDENTS IN DIABETES

To the Editor:—There are several apparent flaws in the paper of Dr. Priscilla White entitled "The Prediction and Prevention of Pregnancy Accidents in Diabetes" in *THE JOURNAL*, Dec. 14, 1940, page 2039.

Before it can be concluded that pregnancy accidents in diabetes can be "prevented by continuous substitutional estrogen and progesterone therapy in replacement doses" and that this treatment is "well within the field of practical therapeutics," it might be well to examine the papers of the Smiths (*Am. J. Obst. & Gynec.* 33:365 [March] 1937; 36:769 [Nov.] 1938; 39:405 [March] 1940) on which Dr. White's work is based. From their work and Dr. White's earlier paper (*Am. J. M. Sc.* 198:482 [Oct.] 1939) one finds that pregnancy accidents may occur in patients with a normal hormonal balance and that abnormal hormonal balances may revert to normal without treatment. Since Dr. White's paper makes no mention of using alternate patients for treatment, how can one tell how many patients were actually benefited by hormone treatment? A recent personal communication from the Smiths states, in fact, that they are strongly of the opinion that any therapeutic trials with estrogen and progesterone should be made with the realization that this field is one of research investigation.

Apparently White feels that her results are so much better than those usually obtained that controls are unnecessary. In this connection I would point out that in a group of 53 pregnant women with diabetes at the Boston Lying-in Hospital there were 8 fetal deaths, or a 15 per cent mortality. These women received no specific treatment other than for the diabetes, and all were delivered normally whenever possible in accordance with the procedure discussed in our paper (Hurwitz and Irving: *Am. J. M. Sc.* 194:85 [July] 1937). This mortality rate compares favorably with the 33 per cent given by White as the usual fetal mortality and with the 13 per cent of her hormone-treated series. As to her statement that obstetric hospitals may report lower rates owing to "a difference in patient clientele . . . obstetric hospitals seeing many short duration cases with onset of diabetes during pregnancy," it may be emphasized that (1) we receive many patients with severe diabetes from other diabetic clinics in Boston which have no obstetric facilities; (2) if we divide our cases into two groups of 27 cases with onset of diabetes before pregnancy and 26 cases with onset of diabetes after pregnancy, we find 4 fetal deaths in each group, or the same mortality rate, 15 per cent; (3) if we classify our diabetic patients according to severity of the diabetes, we find that there were three fetal deaths in the group of 19 women who never required insulin (16 per cent mortality) and only one death in the group of 13 women who required more than 60 units of insulin daily (8 per cent mortality). Apparently, then, the more severe the diabetes, the better the chance for a live baby!

The problem of the high fetal mortality from diabetic pregnancies will be solved by (1) demonstrating a preventable cause of fetal death, which has not been done as yet, or (2) showing a convincing drop of fetal mortality by using a therapeutic measure in alternate cases.

Neither the unqualified recommendation of cesarean section with its attendant higher maternal mortality, which was a previous contribution of Dr. White's (*Surg., Gynec. & Obst.* 61:324 [Sept.] 1935), nor the enthusiastic sponsorship of hormone studies and treatment, which are time consuming, expensive and not readily available to most hospitals, should be accepted without better scientific controls.

DAVID HURWITZ, M.D., Boston.

NOTE.—This letter was submitted to Drs. White and Joslin, who reply:

To the Editor:—Between January 1936 and January 1941 we have had 82 pregnant diabetic patients on whom hormonal studies have been done. Among our 12 consecutive abnormal untreated patients fetal survival was 42 per cent; among 35 consecutive abnormal but treated, as described in my paper, 89 per cent; among 35 normal diabetic patients 91 per cent. In the light of these figures we are unwilling to increase the number of untreated abnormal patients.

Perhaps clarity in the matter of controls was sacrificed for brevity in the article which appeared in *THE JOURNAL*. I myself can see no scientific difference between the selection of alternate patients for therapy and of patients selected as in this work, namely, (1) 12 consecutive abnormal patients untreated, (2) 13 consecutive abnormal patients treated in the matter outlined by the Smiths, (3) 11 consecutive abnormal patients treated with oral preparations, (4) 11 consecutive abnormal patients treated with intramuscular preparations different from group 2. In addition, for controls we have those unfortunate patients subjected to my errors in the estimation of dosages of therapy.

Also because of limited space the character of the diabetes was not given in detail for the individual cases. Such complete data are given on pages 696 and 697 of the seventh edition of "Treatment of Diabetes Mellitus" by Joslin, Root, White and Marble.

As an added control on our series we should like to make determinations of the gonadotropic substance at two week intervals between the twentieth and thirty-second weeks and determinations of the pregnandiol from the twelfth week on diabetic patients not under our immediate care.

The previous contribution in *Surgery, Gynecology and Obstetrics* (61:324 [Sept.] 1935) was not a recommendation of cesarean section per se but a recommendation for a premature delivery to anticipate placental degeneration, since at that time we had no method of differentiating those patients susceptible and those not susceptible to this accident.

Finally, in our series of patients there are well defined causes of fetal death: (1) intra-uterine death associated with mild preeclamptic toxemia and hormonal imbalance, (2) an asphyxial death, without maternal symptoms, in a premature infant whose mother's hormonal balance was abnormal, (3) lethal congenital anomalies, (4) causes of death as in any obstetric practice—hemorrhagic disease of the newborn, pneumonia, erythroblastosis. Causes 1 and 2, "toxic," are, I believe, preventable, 3 not and 4 as in any obstetric series.

PRISCILLA WHITE, M.D., Boston.

To the Editor:—May I add a summary of my experience with pregnant diabetic women?

1. In 1913 I was placed in charge of a pregnant diabetic woman by Dr. B. while he went to Europe. The woman left me for a cultist and on Dr. B.'s return I was upbraided because he found her toxemic and she and her infant died and her husband committed suicide. Thereupon I reported all my cases up to that time of pregnant patients with diabetes (*Boston M. & S. J.* 173:841, 1915).

2. The first notable achievement was Mrs. G. She had had twelve dead babies in succession and at least half of them while she was diabetic. I saw her first in coma in the sixth month of pregnancy. Later her diabetes proved so mild that she was able to omit insulin. As a stunt I brought her into the hospital, put her in a private room, kept her under close supervision and, thanks to Dr. R. S. Titus, who delivered her by cesarean section, she completed her thirteenth pregnancy and had her first living child. Presumably all of her earlier pregnancies could have resulted in the same way if attention to details and money had been available. She taught me

that the patient with ordinary mild diabetes can go through pregnancy successfully if treated with meticulous care.

3. Then came the period of deaths because of giant fetuses—superb babies which were lost immediately before, during or just after confinement. I shall never forget the sight of one of those truly beautiful, big, dead infants, nor do their mothers—because I still have them for patients.

4. Another phase of pregnancy followed the lengthening of lives of diabetic women—young women—and with sorrow now and again macerated fetuses were found at term and we wondered why, and at this time Dr. White came on the scene.

5. Our pregnant diabetic patients henceforth were in many instances hospitalized for the last three months. Some had live babies and some did not, but Dr. White definitely convinced us that deaths were not due to inadequate control of diabetes, to acidosis or to insulin reactions. She observed that among pregnancies eventually ending with dead babies from eight to two weeks before term there had been a brief period of indisposition, a gain in weight, a rise of blood pressure and the presence of albuminuria. In a few days the patient was about as well as ever, but fetal activity had ceased and at delivery weeks later the fetus was macerated. Thereupon clinical surveillance was sharpened. She saw these patients twice a day, and when these signs were observed delivery

Values of Gonadotropic Substances in Pregnancy

Gonadotropic Substance	Cases	Live Babies (per Cent)
Normal	35	91
Abnormal		
Untreated	12	42
Treated	35	89

was instantaneous by cesarean section and our statistics improved. When we postponed delivery we lost the child. Another accident which could not be anticipated was premature delivery with neonatal death.

6. Then followed the hormone studies, suggested by the Smiths to complete their investigation of preeclamptic toxemia. At present there are 82 patients on whom estimations of gonadotropic substances have been made and in addition nearly all have had determinations of the pregnandiol. Twelve of the abnormal patients were untreated. The data are summarized in the table.

With such figures, which kind of supervision, study and treatment ought one to advise for our one hundred young women as they become pregnant, whose duration of diabetes is already fifteen years but with its onset in childhood?

7. Finally, the cases in our series reported by Dr. White are by no means all as spectacular as the following three cases, and another one in an earlier series, but these four deserve mention:

The first patient, with onset of diabetes at 8 years, was first pregnant at 24, with subsequent removal of a dead fetus in London while under the care of men all would recognize as outstanding. During the second pregnancy, when the duration of diabetes was eighteen years, high determinations of gonadotropic substance were made and she was treated for three months: cesarean section with birth of a live baby. The third pregnancy, when the duration of diabetes was twenty years, again with a high determination of gonadotropic substance and similar treatment: cesarean section with birth of a live baby.

The second patient, with onset of diabetes at 10 years, had her first pregnancy after she had had diabetes for twenty-one years, at the age of 31. High determinations of gonadotropic substance and marked preeclamptic toxemia were treated by replacement therapy: a live baby by cesarean section.

The third patient, with onset of diabetes at 24, had five unsuccessful pregnancies—two neonatal deaths, a twelfth week

abortion, a twentieth week miscarriage and one therapeutic abortion. The second viable infant had been especially supervised with the greatest care by a prominent medical man and an obstetrician who delivered her by cesarean section. The baby died eighteen hours after birth. I forbade an abortion in the spring of 1940, and later this patient, whose pregnandiol was found to be low and whose gonadotropic substance was high, was treated with hormones by Dr. White. Otherwise her treatment was as in the second pregnancy, and on December 31 she was delivered by cesarean section by Dr. Titus of a living child. And, incidentally, I will add that all 82 patients were under the supervision and immediate care of Dr. White of our group and nearly all have been delivered by Dr. Titus, and following birth the infants have had the helpful advice of Dr. Warren Sisson.

The fourth patient is now in the hospital, as a volunteer, for some weeks undergoing tests with three new kinds of insulin. When I see her each morning and remember that she has no children, having lost all four in the course of her diabetic pregnancies, all with toxemia prior to 1930, and contrast her situation with the patients with normal gonadotropic substance, or if abnormal treated, of whose infants 89 per cent survived, I am unwilling to suggest to the six patients now awaiting confinement under Dr. White's care that they go without treatment if their gonadotropic substance is abnormal. These patients range in age from 24 to 38, have had diabetes from six months (1) to fifteen years (1) and have been under observation by Dr. White beginning with the second to the sixth month of pregnancy. Of these, all are primiparas.

8. It would be advantageous in this discussion if other patients with onset of diabetes at ages 8 and 10 years and with durations of the disease of eighteen, twenty and twenty-one years who have had successful outcomes of pregnancy could be reported, especially if their values for gonadotropic substance were known. In fact, if further series of cases were published with details such as are shown in the article of Hurwitz and Irving or in our own, it would be advantageous to all.

ELLIOTT P. JOSLIN, M.D., Boston.

MÉNIÈRE'S DISEASE AND HISTAMINE

To the Editor:—I have read, with interest, the query and answer regarding Ménière's disease and histamine which appeared in THE JOURNAL, January 11, page 177. The reference to the preliminary report (Shelden, C. H., and Horton, B. T.: Treatment of Ménière's Disease with Histamine Administered Intravenously, *Proc. Staff Meet., Mayo Clin.* 15:17 [Jan. 10] 1940) is correct as stated but is, in a way, misleading. I presume that the newspaper account referred to by Dr. Odis A. Cook of Anadarko, Okla., had to do with a symposium on the treatment of Ménière's disease in which I took part and which was given before the American College of Surgeons in Chicago, Oct. 22, 1940; this report will appear in *Surgery, Gynecology and Obstetrics* later.

It is not my purpose here to argue the value of the Furstenberg method as compared with the histamine method of treatment of Ménière's disease. These methods will have to rise or fall on their own merits. The majority of our patients selected for treatment with histamine had previously been on a Furstenberg regimen without satisfactory results. I am concerned only with the fact that histamine in a 1:250,000 solution such as we originally suggested can be given intravenously to human subjects with perfect safety. During 1940 we actually gave histamine intravenously in this manner one thousand, two hundred and seventy-two consecutive times without any untoward effects. In no instance have we encountered acute histamine shock. The intravenous administration of histamine in the treatment of

Ménière's disease is so simple that it can be given in the home or as a part of office treatment. Our patients here at the Mayo Clinic are not hospitalized for this purpose. Ampules which contain 2.75 mg. of histamine diphosphate (this is equivalent to 1 mg. of histamine base) are now on the market and, by adding 1 ampule to 250 cc. of physiologic solution of sodium chloride, one has readily available the proper solution to be administered intravenously. We still employ the drip method and are using it daily in our routine work.

BAYARD T. HORTON, M.D., Rochester, Minn.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Failure of Physicians to Remove Foreign Body from Eye; Necessity for Expert Testimony.—While doing some carpentry work the plaintiff got something in his right eye which caused a severe burning pain. After having three roentgenograms taken of his right eye he consulted Dr. Ballard, who examined his eye and then attempted to secure from a local hospital a "giant magnet" used for withdrawing foreign objects from the eye. The physician, however, was refused the use of the instrument, because he was not a member of the staff of that hospital. The next day the plaintiff's eye was again examined with roentgen rays, this time by a Dr. Judson at the Los Angeles County General Hospital. He was denied admission to the county hospital but he was admitted to the California Hospital the following day. There he was placed under the care of a Dr. Boyce whom he had met at the county hospital. Dr. Boyce, after causing additional roentgenograms to be taken by a Dr. Blaine, performed an operation on the plaintiff's eye, assisted by a Dr. Rogers. The operation consisted of an attempt to withdraw the particle in the eye with a magnet followed by an attempt at removal by incision when it was discovered that the foreign body was non-magnetic. The second day after the operation Dr. Boyce took the plaintiff to Drs. Ray and Rodman Irvine, who advised against any further surgical attempt at removal. A few days later Dr. Boyce looked at the eye, which by that time had become swollen shut, and informed the patient that he had "panophthalmitis." Subsequently the plaintiff brought a suit for malpractice against all the physicians named and the California Hospital. From a judgment for the defendants the plaintiff appealed to the district court of appeal, second district, division 1, California.

In the opinion of the district court of appeal, the record was barren of any evidence of negligence by Drs. Judson, Blaine, Ray Irvine and Rodman Irvine or by the defendant hospital. Regarding the alleged malpractice of Drs. Boyce and Rogers, the plaintiff contended that he had gone to the hospital and sought medical aid for only one purpose, to have the foreign body

removed from his eye by the use of the "giant magnet," and that by performing a cutting operation the physicians had exceeded their authority. The court, however, held that the plaintiff had placed himself under the physicians' care for the removal of a particle from his eye and that they resorted to surgery only after the use of the magnet proved ineffective. The court could not agree with the plaintiff's further contention that defendants Boyce and Rogers were negligent in making their diagnosis, in failing to locate the foreign particle and in determining that it was nonmagnetic. A mistake in diagnosis, said the court, would not make a physician liable in the absence of expert testimony of lack of due care, diligence, judgment and skill. The plaintiff had failed to introduce any expert testimony whatever to show that the diagnosis was incorrect or that some method or means other than that used should have been employed in an attempt to remove the foreign body from his eye. In the absence of such testimony, concluded the court, the judgment of the trial court in favor of all the defendants was proper. The judgment of the trial court was therefore affirmed.—*Adams v. Boyce et al.*, 99 P. (2d) 1044 (Calif., 1940).

Malpractice: Failure of Physician to Administer Antitetanus Serum.—The minor plaintiff on May 26, 1936 fell on a stick which penetrated his thigh to the extent of about 5 inches (13 cm.). He was taken for treatment to the defendant physician, who described the wound as "entirely subcutaneous . . . not deep" and "just under the skin." The defendant cleansed the site of the wound externally, swabbed it "all the way to the bottom" with alcohol and also with tincture of iodine, inserted a loose gauze drain which had been soaked with alcohol and then applied a sterile dressing. This treatment was repeated daily for the next three days, during which time the defendant detected no sign of the onset of any infection of a serious nature and considered the condition of the wound to be "very satisfactory." The defendant did not see the plaintiff on the fifth day but on the sixth he administered the same treatment as before. On that occasion the child's stepfather told the defendant that the boy had complained that his jaws hurt him and were stiff. After an examination the defendant said that the boy's jaws were perfectly normal and that there was no rigidity of his neck muscles. Early the next morning the defendant was summoned to the boy's home, found him suffering from a "definite stiffness of the masseter muscle and some of his neck," and took him at once to a hospital. After another physician had seen the patient in his presence, the defendant left the hospital and never again saw the boy professionally. Dr. Shallow, under whose care the child was placed at the hospital, discovered that the boy was suffering from tetanus, or lockjaw, and from an infection of his leg, that his neck was stiff, that he was unable to open his mouth more than half an inch and that he had "generalized rigidity of all the voluntary muscles." Dr. Shallow caused 15,000 units of tetanus antitoxin to be injected and a few hours later did a débridement, excising the infected tract and thus removing "all of the devitalized tissue and some of the sound tissue." Twenty-three days later he performed a "closure" operation to bring the gaping edges of the wound together. The boy stayed in the hospital for about four weeks, during which time he received a total of 750,000 units of antitetanus serum. The boy, by his next friend and mother, and his mother in her own right sued the defendant physician for malpractice. The jury returned a verdict for the physician but the trial court granted a motion for a new trial, and the physician appealed to the Supreme Court of Pennsylvania.

The Supreme Court could not agree with the defendant's contention that the trial court should have directed a verdict in his favor because there was no issue of fact for the jury to decide. The question for determination, said the Supreme Court, was whether or not the plaintiffs had made out a *prima facie* case of malpractice. After discussing many cases defining malpractice, the court quoted with approval from Herzog on Medical Jurisprudence, p. 153, sec. 180, as follows:

If a physician, in the course of his practice, is guilty of any dereliction of duty toward one of his patients, or fails to use proper skill and knowledge in the diagnosis or treatment of a patient's ailment, he is guilty of malpractice. . . . Where there are various recognized methods of treatment the physician is at liberty to follow the one he thinks best, and is not liable for malpractice because expert witnesses give their . . . method would have been preferable. . . .

Departure from approved methods in use will render a physician liable if he injures the patient, no matter how good his intention may have been, so a physician must be very careful in adopting a new method of treatment or one which is not recognized by the school of medicine to which he belongs, for if his treatment should prove injurious to the patient he would be liable for not having used recognized methods.

At the hearing before the trial court, continued the court, the expert witnesses for both the plaintiffs and the defendant admitted that the proper treatment for a punctured wound required that it be incised to its depth and thoroughly drained and that a subcutaneous injection of tetanus antitoxin be administered to the patient. From there on, however, the evidence was in irreconcilable conflict. Five physicians who testified for the plaintiffs said that the boy's injury was a punctured wound and indicated that the defendant was negligent in failing to administer antitetanus serum. Nine physicians who had been called by the defendant, however, testified that a substantial group of physicians in good standing in Philadelphia in May 1936 would have rendered the same treatment which the defendant had administered in this case and that such was "a reasonably successful" treatment. If, said the court, the boy's wound was a punctured wound, the medical testimony was in accord that the treatment administered by the defendant would not be proper. If it was not a punctured wound, the medical testimony was in conflict as to whether or not the defendant's treatment was in accord with good medical practice. The court held that the evidence showed that the defendant had not used the approved method of treating a punctured wound and so the plaintiffs had made out a *prima facie* case if there was also evidence that the boy's wound was a punctured wound. In the opinion of the court the physicians who testified for the plaintiffs supplied that evidence. The size of the wound, 5 inches in depth with a diameter of $\frac{1}{2}$ inch, indicated that it was a punctured wound. The defendant's own description of the wound as "a punctured wound and shallow, being next to the surface, and just under the skin, about five inches in length," fits perfectly into the following medical definition of a punctured wound, in Christopher's "Minor Surgery," ed. 2, p. 30:

Punctured wounds are those in which the orifice is relatively small compared to the depth of the wound. . . . The entrance rapidly seals over and the depths of the wound which have been invaded by the nail or missile are excellent soil for anaerobic organisms.

In the judgment of the court the question as to whether or not the boy's wound was a punctured one should have been submitted to the jury with proper instructions.

The defendant also contended that there was no evidence showing a causal connection between his malpractice and the plaintiff's lockjaw. The court held, however, that the medical testimony clearly supported the inference that an earlier administration of the antitetanus serum, at the time the defendant first attended the boy, would have averted the onset of lockjaw. The successful treatment of this patient in the hospital with tetanus antitoxin, although administered belatedly, proved its potency. The court concluded, therefore, that the granting of a new trial was proper and so it affirmed the order of the lower court.—*Hodgson v. Bigelow*, 7 A. (2d) 338 (Pa., 1939).

Northern Tri-State Medical Association, Tiffin, Ohio, Apr. 8. Dr. E. Benjamin Gillette, 320 Michigan St., Toledo, Ohio, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Vitamin E for Amyotrophic Lateral Sclerosis.—Amyotrophic lateral sclerosis has been regarded invariably as progressive and ultimately fatal from bulbar paralysis within from two to three years. Wechsler reports 20 cases in which treatment with tocopherol acetate was given. The results seem to confirm his preliminary report of 1940 regarding the curative effects of vitamin E. Treatment thus far consisted of 30 and later of 50 mg. daily of Ephynal or alpha-tocopherol acetate by mouth. Some patients required from 100 to 200 mg. of the preparation. About one half of the patients had 50 mg. of tocopherol in oil injected daily intramuscularly. All patients received food rich in vitamin E: lettuce, kale, whole wheat bread, coarse cereals, butter, bananas, fresh corn, fresh peas and beans, yolks of eggs and fat beef. Because vitamin E is fat soluble, two 5 grain (0.32 Gm.) pills of bile salts were given daily. In 2 instances discontinuing the vitamin brought about a relapse. This was promptly reversed when vitamin E was readministered. Only two such experiments were purposely undertaken. Eleven of the 20 patients showed varying degrees of improvement; 2 seem to have recovered, 4 showed

marked improvement and 5 were moderately improved. Three patients may be said to have the disease arrested. Two patients with an advanced stage of the disease and bulbar signs died; 1 of these began to show improvement in his bulbar signs but died of pneumonia. At necropsy, cancer of the pancreas was found. The other patient died of bulbar involvement. Two patients have definitely grown worse and, of the remaining 2, 1 is worse after initial improvement and the other is slightly worse. The fibrillations are apt to disappear first, thus indicating a recession in the activity of the disease process. The patients who recovered showed fairly rapid improvement. It appears that treatment with the synthetic or the natural vitamin E must be permanent, unless the cause of failure to absorb (of which there is some evidence) is discovered and removed. Why, in view of the fact that natural vitamin E is so prevalent, there is failure of absorption and why if there is failure it occurs only in certain persons cannot be answered at this time. Two facts appear certain: vitamin E deficiency, probably of the alphas-tocopherol factor, is one cause of amyotrophic lateral sclerosis and administration of vitamin E may be a specific treatment. The studies suggest the possible treatment of other diseases of the nervous system which for want of better knowledge are called degenerative. It may be that some "degenerative" disease will be found to result from the privation of specific vitamins, though other factors may play additional roles; for example, the absence of vitamin B₆ in "degenerative" paralysis agitans not of the arteriosclerotic or inflammatory types.

Sulfathiazole for Pneumococcal Pneumonia.—Volini and his associates treated 169 patients having pneumococcal pneumonia with sulfathiazole by mouth. There were 9 deaths, a 5.3 per cent mortality. A control series in which sulfapyridine and serum combined were used showed a mortality of 4.2 per cent. The mortality in the bacteremic group was higher with sulfapyridine treatment. Sulfathiazole is apparently as effective as sulfapyridine. Sulfapyridine appeared more effective in type I and III infections, whereas sulfathiazole produced better results in type II and VII infections. Nausea, vomiting and the other common toxic manifestations of sulfapyridine therapy were much less frequent with sulfathiazole. Drug fever and especially the papulonodular eruption with conjunctivitis were the severe toxic manifestations of sulfathiazole medication. The blood concentration level varied considerably in the same patient on a maintenance dose of 1 Gm. every four hours.

Esophageal Changes Due to Psychic Factors.—Faulkner demonstrated that the esophagus undergoes definite changes in response to emotional upsets. This was observed with an esophagoscope in 13 patients seeking relief for symptoms ascribed to one or more of the organic systems. All the patients were referred, some because of esophageal complaints and others because of the author's interest in the study. Disturbing thoughts and emotions produced esophageal spasm. The spasm increased and the esophageal lumen narrowed or closed by suggestions calling forth destructive emotions, such as grief, anger, anxiety, apprehension, fear and spiritual imprisonment. The spasm relaxed and the lumen widened on proposals eliciting happiness, elation, enthusiasm, contentment and security. The esophageal reaction and alteration in the spasm was directly related to the patient's personal interest in the problem; conversely, situations in which the patient had no vital interest were incapable of eliciting an esophageal reflex. In addition to causing uniform spasm of the esophagus, the author believes that disturbing emotional influences are underlying factors in certain esophageal strictures, cardiospasm and so-called idiopathic pressure diverticula of the esophagus.

Roentgen Therapy for Herpes Zoster.—McCombs and his colleagues obtained success with roentgen rays in the treatment of herpes zoster. Of their 123 patients, 72 were given roentgen therapy. Of the 51 in the control group, 14 received injections of solution of posterior pituitary and others were given sedatives and salves or were merely observed to determine the duration and severity of the disease. Their present method of treatment is to give the patient 200 roentgens daily or every other day, for five or six treatments, using 200 kilovolts through 1 mm. of copper and 1 mm. of aluminum filter

at a distance of 50 cm. in a 6 by 15 cm. portal directly over the spinal root ganglions of the nerves involved. Of the patients treated 21 had had their symptoms for from one to three days, 23 for four to seven days, 11 for from eight to fourteen days, 4 for from fifteen to twenty-eight days and the remaining 13 had had the herpetic syndrome for more than a month. Of the patients treated with roentgen rays 46 per cent were cured within eight to fourteen days, whereas only 16 per cent of the control group were relieved within this period. It required from twenty-eight to sixty days to cure 35 per cent of the latter group, whereas 56 per cent of the patients treated with roentgen rays were cured within this time; 9 required more than a month for cure. Of these only 1 was seen within thirty days of the onset of the disease, the others in from one to eight months after the onset of symptoms. Thirty-nine, or 89 per cent, of the 44 patients treated within the first seven days of the disease were completely relieved; 2 were improved and 3 received no benefit. Of the 11 treated between the eighth and the fourteenth day of onset, 8 were relieved completely, 2 were partially benefited and 1 reported failure. Of the 4 treated between the fifteenth and the twenty-eighth day, 2 were cured and 2 reported failure. Of the 13 treated after the twenty-ninth day, 7 were cured, 1 was partially benefited and 5 obtained no relief. Herpes zoster must be treated promptly, as the cures in the first seven days were 89 per cent as compared to only 50 per cent after fourteen days. Symptoms may be exaggerated after the first treatment, and therefore patients must be warned of this reaction and advised that improvement will follow subsequent treatments. Patients may want to desist from roentgen therapy after a few treatments because pain is relieved and the local lesions do not show further spread. It is important to insist on the full course, as after a brief interval an occasional insufficiently treated patient has recurrence of pain and paresthesias. These were relieved by further treatment.

Arsenic and Subacute Encephalomyelitis.—As considerable arsenic was found in most brains from subacute fatal cases of encephalomyelitis, Ecker and Kernohan studied the possible significance of this observation by correlating the clinical, pathologic and chemical features of the cases. The features of fatal encephalomyelitis frequently appear like those of a continuous action of some toxic agent. It is probable that many persons who are exposed continuously to arsenic from a multitude of legitimate everyday sources may be slowly poisoned because of its cumulative effects, making "chemical encephalitis" not only possible but probably not rare. The symptoms of arsenism are primarily headache and physical and mental fatigue, probably with accompanying dizziness,

restlessness, excitability and mental dulness, a manifestation of cerebral symptoms. The authors studied three series of cases; 13 cases of known arsenical poisoning, a miscellaneous main control group of 24 cases listed in the neuropathologic files under the heading of "encephalitis" (the brains of which were tested for the presence of arsenic; 15 contained no arsenic and 9 from 0.02 to 0.05 mg. per hundred grams of tissue) and 12 cases in which more than 0.1 mg. of arsenic per hundred grams of tissue was found and this was considered significant. As a further control the brains in 6 fatal cases of malignant hypertension were studied and less than 0.02 mg. of arsenic per hundred grams of brain tissue was found in each instance. This fact is strong evidence against the hypothesis that arsenic is deposited in the brain in all cases of chronic cerebral damage. This view is also substantiated by the 24 other instances of long-standing cerebral disease which comprise the main control group. The 13 cases of known arsenical poisoning and the 12 with more than 0.1 mg. of arsenic per hundred grams of brain tissue presented precisely the same diffuse cerebral symptoms (fatigue, headache, vertigo, drowsiness and impairment of mental activity) which constitute a syndrome that is summarized as "progressive diffuse cerebral failure." The clinical, pathologic and chemical observations that concern the 12 cases are consistent with the hypothesis that they represent instances of chronic arsenical poisoning. The abnormally large amounts of arsenic found in the brains do not in themselves imply that arsenic is the cause of subacute encephalomyelitis, as it is possible that the arsenic ingested by most Americans might be deposited at a locus minoris resistentiae in greatest concentration. To consider this possibility, brains in 6 cases of malignant hypertension were studied. They resembled the cases of encephalitis in duration, symptoms and pathologic alterations. The fact that an appreciable amount of arsenic was not found in any of these brains is strong evidence against the likelihood that arsenic is deposited in all brains damaged over a period of months. Further evidence for or against the hypothesis can be obtained by microscopic studies of brains from recognized cases of chronic arsenism and by determining the arsenic content in the excreta and tissues, especially the nervous system and hair, in other cases of subacute or chronic meningoencephalomyelitis.

Quinine and Prostigmine Methylsulfate in Paralysis Agitans.—Milhorat observed effects of quinine and prostigmine methylsulfate on the muscular rigidity of 8 patients with paralysis agitans. Two of the patients had only slight stiffness of a few groups of muscles, 4 had moderate rigidity of two or more extremities and the stiffness of 2 involved most of the voluntary musculature. Quinine was administered for periods of from two weeks to several months, with several alternate periods of control and of quinine administration. The dose in most instances was 0.3 Gm. of quinine sulfate orally two or three times a day. Six of the patients were receiving and continued to receive scopolamine daily. The muscular rigidity of 2 patients was much decreased. The muscular pain of both patients and the rigidity of the jaw muscles of 1, which had resulted in continual drooling and in malnutrition, were relieved considerably. Quinine was more effective for muscular pain than acetylsalicylic acid. The effect of quinine on tremor was slight in 1 patient and was not demonstrable in the other. Moderate reduction of muscular stiffness of 2 patients was observed; in 1 of these the muscular rigidity involved most of the voluntary muscles. Both patients complained of muscular pain, which was much decreased after taking quinine. Tremor was decreased slightly in the patient with the advanced stage of the disease but was unaffected in the other. In 4 patients the effect was absent or only slight. In 2 of these muscular rigidity was slight and in 2 moderate. Patients in whom quinine had a definite effect continued to derive benefit for from one to four months, after which quinine had a decreasing effect. In some instances the effect diminished until it was practically absent. After the drug was discontinued for a few weeks its effect again became evident. The effect of prostigmine methylsulfate on muscular rigidity was studied on 4 patients. The usual dose of the drug was 1.5 mg., given subcutaneously. Usually its administration was followed, within fifteen minutes, by a considerable increase in rigidity and tremor. In 1 patient with symptoms of only moderate severity the clinical picture rapidly developed into one resembling a far advanced stage.

Muscular rigidity of cogwheel character became severe in all extremities, and tremor which had previously been moderate became violent. The patient experienced diplopia. In another patient cogwheel rigidity developed in an extremity which was previously unaffected. Atropine abolished the effects of prostigmine methylsulfate and within ten minutes the symptoms returned to their previous status. In patients with congenital myotonia and atrophic myotonia an increase in the inability of the muscles to relax was observed after prostigmine methylsulfate caused an initial forceful contraction. The effect of prostigmine methylsulfate on muscular rigidity of paralysis agitans is not related to any unusual activity of the cholinesterase in this condition. It is probable that the effect of quinine on muscular function in cases of "myotonia" and paralysis agitans is the result of the antagonistic action of the drug to cholinergic nerve stimulation.

Personality Changes After Carbon Monoxide Poisoning.—Nielsen and Ingham cite 4 cases of carbon monoxide poisoning in which there were unmistakable signs of basal ganglion involvement. The first two poisonings followed suicidal attempts, one was accidental and the cause of the fourth is not mentioned. After the acute episode the patients recovered to a variable degree, then relapsed and the 3 who have survived have continued in a state of complete loss of affect. They are inattentive, disinterested, without initiative or sense of responsibility and completely disabled for work. Parkinsonian symptoms are in evidence. The brain in the fatal case showed bilateral necrosis of the globus pallidus (which is in keeping with such poisoning) and also gross lesions in the white matter and cortex. In this case the initial coma of the asphyxia was followed by improvement, although apathy and loss of emotional reaction remained. There was a relapse two weeks after the initial coma, and death occurred one month after the acute episode.

*Recurrent Hyperthyroidism. R. L. Hane, Fort Wayne.—p. 675.

Recurrent Hyperthyroidism.—Hane defines true recurrent hyperthyroidism as that which arises after a postoperative period free of symptoms, from the very nature of the disease itself, while persistent hyperthyroidism is a reflection on the technic employed. Recurrent hyperthyroidism is largely concerned with diffusely hyperplastic or exophthalmic types of goiter. When

secondary symptoms appear after a nodular or adenomatous goiter has been removed, either the thyroid remnants left have been of the hyperplastic type or small adenomas have been left which later grow and cause excessive secretion. Some workers explain all recurrences as due to inadequate surgery. Inadequate exposure of the lateral lobes of the thyroid, failure to search for retrotracheal projections and pyramidal lobes or ultraconservatism in removal of tissue is often productive of incomplete relief of symptoms. The author reviews cases from St. Joseph Hospital in which treatment tends to be conservative; many patients are operated on only after irradiation and medical measures have failed. From January 1925 to July 1940 there were 209 patients treated by subtotal thyroidectomy; there were 91 adenomatous goiters, 104 diffusely hyperplastic or exophthalmic goiters, 6 simple colloid goiters, 5 carcinomas and 1 struma lymphomatosa (Hashimoto). There were 11 deaths, giving a gross mortality rate of 5.26 per cent. Eight of the patients were being operated on the second time and 1 the third time. Of these 9 (4.3 per cent) patients, 5 had goiters of the diffusely hyperplastic or exophthalmic type and 4 of the adenomatous type. The intervals between the primary and secondary operations in the adenomatous goiters were ten, twelve, fourteen and nineteen years respectively. Of the diffusely hyperplastic or exophthalmic goiters requiring secondary surgery, 2 should be classified as persistent hyperthyroidism; in 1 lobectomy and double ligation preceded the secondary operation by five years; in the other hemorrhage encountered at surgery prevented satisfactory completion of the initial operation. There were three true recurrences of exophthalmic goiter. It seems that a few patients with exophthalmic goiter seem destined to recurrent symptoms and thus parallel the experience of certain patients with duodenal ulcer who continue to have recurrent ulcers in spite of increasingly radical surgery. A special study was made of the 162 patients operated on from 1925 to 1935 inclusive. Questionnaires were sent inquiring as to the appearance of symptoms since surgical intervention and the necessity of further operation. There were 6 deaths among these patients, a mortality rate of 3.7 per cent. It was possible to trace 122 of the 162 patients; 62 who had diffusely hyperplastic or exophthalmic goiter, 56 with nodular or adenomatous goiter, 2 with colloid goiter and 2 with carcinomas. One patient with a typical nodular goiter with mild hyperthyroidism had required a second operation. Ten years had elapsed between the two operations. There were 7 additional patients who reported either a return of symptoms or incomplete relief; 5 of these had goiters of the exophthalmic type, 1 an adenomatous goiter and 1 a carcinoma. Of the exophthalmic goiters giving further symptoms 2, or 3.2 per cent, can definitely be considered true recurrent hyperthyroidism and 3, or 4.8 per cent, persistent hyperthyroidism. Four of the 5 patients with exophthalmic goiters who had further symptoms have been treated conservatively and have improved. The postoperative management of these patients should include regulation of future activities. If any importance is to be placed on emotional or nervous drive as a primary etiologic factor in hyperthyroidism, it is only reasonable to eliminate it as far as possible. Any failure of normal postoperative improvement calls for increased rest and, if necessary, some form of sedation. When mild recurrent symptoms are manifest, a regimen of iodine medication, rest and sedatives is continued. Roentgen therapy may be tried and, if ineffective, further surgical intervention should be considered.

End Results in Intestinal Cancer.—Cattell analyzes the end results of 270 patients with cancer of the large intestine who had been observed for from five to nine years. The cancer of 172 was located in the rectum or rectosigmoid, and of 98 in the colon or sigmoid colon. The operability rate in the rectal cases was 57 per cent (98 resections) and for the colon cases 55 per cent (54 resections). All patients who refused operation, whether favorable or unfavorable, are included among the nonresected group. Some of these had later resections elsewhere. A modified Mikulicz resection was performed on 51 of the 54 patients with colon cancer; in 3 a preliminary anastomosis was done around the lesion, followed by resection. There were 8 operative deaths among the 51 resections. Twenty-seven patients showed no evidence of recurrence for from five to nine years after operation, 14 patients are known to be dead of recurrence, 1 died one year after operation of pneumonia, without recurrence, and no observation of 1 was possible. There were no deaths among the 3 patients having two stage resections. Two were free of recurrence when observed five years after operation, and 1 died of recurrence four years after operation. Thirty of the 44 patients with carcinoma of the colon in whom resection could not be done either had colostomy or anastomosis around the lesion. There were 4 operative deaths, and only 2 patients were known to live more than one year after operation. Six had explorations only, and no operation was performed on 8. All these patients were dead within six months. Four types of operation (two stage abdominoperineal resection for 55, one stage abdominoperineal resection for 7, anterior or abdominal resection for 12 and perineal or posterior resection for 24) were employed for 98 of the patients having carcinoma of the rectosigmoid or rectum. The composite end results are 14.3 per cent operative mortality, 37.8 per cent of deaths from recurrence, in an additional 4.1 per cent the result was either unknown or

death occurred from another cause, and 43.8 per cent showed no recurrence for from five to nine years. Of the 74 patients with rectosigmoid and rectal cancer who did not have resection, simple colostomy was done in 50; 32 of them died in one year or less and 6 died during the second postoperative year. Seven of the remaining patients had only exploratory procedures and 17 had no operation or refused operation. Of the 270 patients, 130 of those having resections survived the operation and 72, or 55.4 per cent of them, were free from recurrence. Radical resection is recommended for all patients having carcinoma of the large intestine.

Syphilis and Alcoholism.—In order to determine the incidence of syphilis among alcohol addicts, Orenstein and Goldfarb obtained a detailed history of venereal infection or treatment and a blood Wassermann test on discharge of 1,001 consecutive admissions to the alcohol wards of Bellevue Hospital. The percentage of syphilitic infection among 680 white male patients was 3.3, and among the 100 Negro males it was 30. There were evidences of syphilis in 8.5 per cent of the white female patients and in 55 per cent of the Negro women. This is in contrast to the incidence of syphilitic infection among the white population, which has been variously reported from 1 to 4 per cent and up to 15 per cent for Negroes. The authors believe that the especially high incidence of syphilitic infection among the women is related to the fact that they are exposed to sexual aggressions while intoxicated.

Conditioned Reflex Therapy for Alcohol Addiction.—According to Voegtlin and his associates, a review of the results and theory of treating alcohol addicts by the conditioned reflex principle shows that disappointing results obtained by earlier workers were due to failure to consider one or more of the following fundamentals: 1. Successful conditioning demands a most exact and detailed technic, which cannot be accomplished without a literal application of Pavlov's principles and the acquisition of skill and judgment which result only from experience. 2. Attempts to establish aversion to liquors by the conditioned reflex by adulterating the drinks to be ingested with nauseants is not successful because of the narcotic effect of the alcohol that is absorbed, and it allows the development of a distaste only for the adulterated drink. This type of therapy is

unscientific, for it allows the alternation of positive (drugged liquor) and negative (undrugged liquor) stimuli. 3. Apomorphine is unsuitable as the unconditioned (nauseating) stimulus because its emetic and nauseant action is too brief and because of its hypnotic or euphoric after-effects. It is not always a safe drug to administer to alcohol addicts. 4. The conditioning séance must be carried out in a specially constructed treatment room from which all extraneous stimuli are excluded while the olfactory, visual and gustatory stimuli related to drinking are stressed. 5. All conceivable types of liquor must be utilized, for if an aversion is created toward only one or two liquors an early relapse is to be expected. 6. The patient must be taught to discriminate between noxious and innoxious beverages at the subconscious level of neural activity. 7. A proper technic requires the ability to administer the conditioned stimulus (liquor) within a few seconds before the unconditioned stimulus (nausea) manifests itself. A proper degree of conditioning is most important, as it is easy to "overcondition" the patient, with resulting loss of aversion. 8. Reinforcement of the conditioned reflex by systematic follow-up treatment is necessary if optimal results are to be obtained. 9. If the foregoing is carried out, a cure rate of more than 64 per cent may be anticipated; this may be raised by reinforcement procedures.

Microscopic Proof of Malignant Lung Tumors.—

According to Craver, since the microscope gives the only proof of the existence of malignant pulmonary tumors, no treatment should be undertaken until evidence is obtained and the necessity for treatment, which is radical and hazardous, is definite. Biopsy specimens of pulmonary tumors are often difficult to obtain, as many are not accessible to the bronchoscope. Thoracotomy or examination of pleural exudates is likely to be resorted to. In view of the shortcomings of these diagnostic procedures, the staff at Memorial Hospital began more than a decade ago to apply aspiration biopsy to pulmonary tumors, feeling that this procedure presented a means of obtaining a diagnosis quickly, with comparatively little discomfort or danger to the patient, and particularly without employing thoracotomy in inoperable cases. A study yielded 175 microscopically proved cases from a total of 401 cases. After 1932 the number of proved cases for the first time, and steadily thereafter, exceeded the number of unproved ones. The methods relied on for diagnosis in preparing for treatment the 175 patients were thoracotomy, bronchoscopy, aspiration biopsy and postmortem confirmation. Aspiration biopsy established the diagnosis in 64 cases during life. Two of the 175 patients happened to save gross pieces of tissue which they had expectorated. These pieces permitted sectioning in the routine manner and gave positive diagnoses. From 1935 to July 1939, aspiration biopsy accounted for 51.6 per cent of all the microscopically proved cases, or 49 of 95 cases. A detailed account of the technic of aspiration biopsy of the lung is given and its hazards are discussed. In the Memorial Hospital series, of a total of 230 lung aspirations there has been no case of empyema, pulmonary abscess or growth of tumor along the puncture tract. Two instances of air embolism resulting from pulmonary puncture have been encountered. On the theory that air bubbles introduced into the pulmonary venous system and thus via the left side of the heart into the systemic circulation tend to ascend, it is recommended that all punctures be done with the patient lying flat or in a slight Trendelenburg position so as to minimize the danger of air bubbles going cephalad. Needles of the smallest caliber consistent with the minimal danger of breakage are to be employed. Successful aspirations

can be obtained from subcutaneous tumors even with hypodermic needles if the proper technic is employed. Development of technic of searching sputum for tumor cells is worthy of trial.

Primary Carcinoma of Lung.—Ochsner and DeBakey state that in a decade the prognosis of primary carcinoma of lung has been reversed from absolutely hopeless to relatively favorable. The fact that a number of patients living and well five years or more after operation is due chiefly to the rapid technical strides made in thoracic surgery. Its developments are now in such a perfected state that the most important consideration is early diagnosis. The consensus is that the only curative treatment of primary pulmonary carcinoma is surgical extirpation. Any procedure short of total pneumonectomy is irrational, as it is the only procedure which removes adequately the primary focus and the regional lymph nodes. Lobectomy does not extirpate them. The high incidence of lymph node involvement is seen in the following: Of 2,579 collected cases the regional lymph nodes were involved in 75.9 per cent. In Forni's collected cases of pneumonectomy the incidence of recurrence was 9 per cent, as compared to 25.8 per cent following lobectomy. Operability in pulmonary carcinoma depends on the time elapsed from the onset of symptoms. Many cases are inoperable when first seen. Factors which preclude resection are distant metastases, involvement of the contralateral lung, evidence of advanced mediastinal involvement, fixation of the trachea and bronchi, widening of the carina, extension of the process above the bifurcation, involvement of the phrenic or vagus nerves and extension to the pleura. Debility and advanced age also contraindicate radical extirpation. Borderline cases should be given the benefit of exploration even at the risk of closing up many of them without extirpation, as in these instances it is the only means by which operability can be determined. The operability is still far too low, probably because of the fact that diagnosis is late. In 139 collected cases 68 (49 per cent) were operable, whereas 19 (63.3 per cent) of the authors' 30 cases were operable. They believe that their higher incidence of operability is probably due to the fact that they explored apparently inoperable cases which at the time of operation were found operable. A preliminary artificial pneumothorax is extremely desirable in preparing these patients for pneumonectomy, as is general rehabilitation. For pneumonectomy the most important requirements are complete control of intrapulmonic pressure, adequate facilities for aspiration of respiratory secretions, maintenance of quiet respirations and high oxygenation, avoidance of distressing cough reflex and rapid return to consciousness after operation. For this a highly trained and skilful anesthetist is obligatory. The anesthetic agent should permit the administration of a high concentration of oxygen; cyclopropane and ether permit this. The authors prefer cyclopropane. Total removal of the involved lung and the mediastinal lymph nodes can be adequately performed only by individual ligation of the hilar structures. The various approaches in pneumonectomy, the technic of exposure, isolation and ligation of the hilar structures are described, illustrated and evaluated. Analysis of the 139 collected and the 19 personal cases show a general mortality of 45 per cent. The most frequent causes of death are cardiac and pleuropulmonary complications. A follow-up of 57 of 73 of the collected series reveals that 70 per cent of the patients are still living, as are 7 of the authors' 10 patients who recovered from operation, the longest survival being four and one half years.

Perforation of Small Intestine by Swallowed Foreign Bodies.—Melville points out features of perforation of the small intestine by an ingested foreign body which will aid in the correct diagnosis when the patient is first seen. He reports 5 cases and 1 of perforation of Meckel's diverticulum by an ingested foreign body. Operation was performed by the author on 3 of these patients. Examination of the records of the last six years of the Alfred Hospital revealed 2 further cases; 1 of these was of Meckel's diverticulum. The sixth patient was under the care of K. E. Rex and C. A. M. Renou, who supplied the details. In all except the 1 case the terminal part of the ileum was perforated. The condition is not common and apparently has never been diagnosed before operation or necropsy. This is because of its close similarity to acute appendicitis in some cases; in others the clinical features have been too confusing to suggest the origin of peritonitis. This group may also be confusing because similar cases are rare in any one surgeon's experience. To aid in the diagnosis of the condition a theoretical postulate consisting of colic, peritonitis and a locus in the lower part of the abdomen is advanced. Many of the acute cases approximate this concept. The influence of the omentum and of the effective size of the perforation modifies the features of a typical case. Although uncommon, perforation of the small intestine by a foreign body should be kept in mind as a possible cause of obscure peritonitis. The author reviews 9 cases from the literature.

Treatment of Burn Shock with Plasma and Serum.—Black treated 7 severely burned or scalded patients with infusions of plasma and/or serum. The plasma used was obtained by separation from blood taken into standard Medical Reserve Corps bottles containing 180 cc. of citrate solution, the final product being "half-strength plasma." The serum protein was made up by the addition of sterile water to dried serum, and the solution used was four times the concentration of the original serum. Blood and plasma volume, hematocrit, hemoglobin and erythrocytes, protein and albumin, chloride, bicarbonate and urea, sodium and potassium were determined before and after the infusion of plasma or serum and after complete recovery from the burn. Records were kept of the pulse and blood pressure and of the patient's general condition. With the exception of the sixth patient, whose injury was slight in extent and degree, the burn was followed in less than an hour by severe and increasing classic shock. There was no remission after the onset of shock justifying a distinction between primary and secondary shock. Three infusions of from 150 to 300 cc. of the serum and six infusions of from 500 to 2,000 cc. of the plasma were given the 7 patients. The fourth patient, who was burned over more than half the body surface, did not respond to concentrated serum infusion. The other eight infusions were

all followed by definite, in some cases dramatic, improvement. Peripheral cyanosis disappeared, the veins filled out and mental apathy gave place to alertness. The mental quickening was sometimes evidenced by a new consciousness of pain in the burned area. Patients were better able to take fluids by mouth and to retain them. The blood pressures rose. No reaction followed serum or plasma infusion. The results with four times normal serum were less favorable than those with plasma; 1 of the 3 patients treated with concentrated serum died and the other 2 required an infusion of dilute plasma later. The period during which patients with burns are in jeopardy from shock extends for some forty-eight or seventy-two hours after the accident. The pathologically increased capillary permeability, the fundamental lesion in shock, can be improved by maintaining during the danger period an adequate blood volume by replacing the protein and fluid which are lost. This maintenance prevents the onset of irreversible tissue changes. Since shock is an intractable condition plasma should be given early, before general circulatory changes occur. In patients who have had no hemorrhage the determination of hemoglobin offers a sensitive measure of the amount of plasma lost. For approximate calculation of the plasma deficit it is justifiable to assume a hemoglobin percentage of 100 and a blood volume of 5 liters, of which 3 liters is plasma. The increased hemoglobin value observed bears the same ratio to the initial value as the initial value for blood volume does to the new blood volume, since the erythrocyte volume remains unchanged. This may be expressed by $\frac{Hb_2}{Hb_1} = \frac{BV_1}{BV_2}$ or, substituting the assumed values, $\frac{Hb_2}{100} = \frac{5}{(5-x)}$, where Hb_2 is the observed hemoglobin value after the burn and x is the amount of plasma lost; x can be calculated easily if Hb_2 is known. Patients who show a hemoconcentration of more than 10 per cent and in whom the burn involves an area equal to one limb or greater should be given plasma or serum. For patients with shock an overdose of fluid is as dangerous as an underdose, though the danger is less with protein-containing infusions than with saline solutions, which should not be used. To avoid this danger the approximate deficit in the plasma volume should be calculated on admission and the citrated plasma given intravenously while preparations are made for cleansing the burned area. After the burned areas are cleansed, the hemoglobin estimation should be repeated and if hemoconcentration exceeds 10 per cent a further appropriate amount of plasma should be given. This means that in the average case of extensive burns a liter of plasma should be given before the burns are debrided, while after debridement as much as 2 or 3 liters may be required; such an amount is best given by cannula at a drip speed of about a hundred drops a minute. It is necessary to examine the patient every few hours during the second infusion to prevent overdose. Engorgement of the neck veins is a valuable sign that too much fluid is being given. The intravenous drip should not be maintained for more than one or at most two days, as by then fluid by mouth should be possible and the danger of death from shock is diminishing, while the risk of pneumonia, which is aggravated by pulmonary edema, is becoming more imminent. For patients with burns, as for others with disordered water metabolism, records of fluid balance should be kept, and the amount of fluid given by mouth should be regulated on this basis.

Silver Nitrate, Tannic Acid and Gentian Violet for Burns.—Ross and Hulbert report the results they obtained with silver nitrate, tannic acid and gentian violet in the treatment of 5 severely burned airmen; 4 were admitted to their care within eight and 1 forty-eight hours after injury. The treatment followed in each instance closely paralleled that advocated by Dennison in 1939. The immediate coagulation method proved completely successful in their 5 cases. Sepsis and pulmonary complications were absent, despite the variety of anesthetics used. The method is a definite advance on the treatment of burns, especially in war surgery. Thorough gentle cleansing of all loose epithelium is essential before the solutions are applied. Splinting the burned limbs to ensure rest and to prevent contractions is essential. No other dressings are required. The results justify the exacting routine of repeated applications of gentian violet, silver nitrate and tannic acid solutions to produce a dry smooth coagulum.

Mass Roentgenography in Practice.—The object of mass roentgenography, according to Heaf, is to discover cases of pulmonary tuberculosis. It should not be considered as a means of determining the incidence of tuberculosis but as an instrument for combating the spread of infection by revealing the hidden active cases among the apparently healthy population. Roentgenography should be presented to the public as part of a general fitness campaign rather than a search for cases of tuberculosis. An organization for the rehabilitation of the abnormal cases discovered must be promoted. Inpatient observation and treatment must be avoided where possible and every effort made to prevent the development of invalidism. Attention should be given to the domestic environment, employment, leisure and daily routine of those whose chests show lesions which are or may be of clinical significance. The diagnosis of chest lesions discovered by mass roentgenography may have far-reaching consequences, and doubtful cases should be submitted to a board of three specialists, of whom the tuberculosis officer should be one. Sufficient accommodation should be available after the war for the observation and treatment of active cases. Investigations into domiciliary conditions and employment, training in suitable occupations, and redistribution of labor might be under the management of a national rehabilitation board, assisted by industrial organizations. Cases needing care because of the presence of tuberculosis would be handed over to the public health authorities for observation and treatment. Since the main benefit of the scheme would fall to industry, industrial concerns should help financially in the inauguration and maintenance of the scheme, while the treatment and part of the rehabilitation costs might be borne by the local authorities.

Pneumococcic Meningitis Since Sulfapyridine.—Coleman summarizes in tabular form most of the published cases of pneumococcic meningitis in which sulfapyridine was administered and reports 2 cases of his own. The tabulated cases number 27. The author finds that sulfapyridine has reduced the case mortality of pneumococcic meningitis from close on 100 per cent to about 35 per cent. To be effective, sulfapyridine must be given in large doses at the outset; at least 6 Gm. a day should be given to an adult for the first four or five days, after which the dose can gradually be decreased. There is no reliable clinical evidence that antipneumococcus serum is of value in a straightforward case. Frequent lumbar puncture should be avoided, except where it is indicated for the relief of the patient. Sulfapyridine should be continued in decreasing doses for at least a week after the temperature has returned to normal. A patient who is going to recover will nearly always show some signs of clinical improvement within the first three or four days; and, if improvement is noticed at all, the patient almost always makes a complete recovery in the end. Provided dosage has been adequate, cases proving resistant to treatment are due either to a strain of pneumococci insensitive to sulfapyridine or to a strain which has become tolerant to the drug.

Chemotherapy of Cerebrospinal Fever in Childhood.—Williams reports 102 cases of cerebrospinal fever in patients under 16 years of age. Lumbar puncture was performed in

every case on admission, and the organism was typed. In the case of turbid fluid, sulfanilamide was given immediately. Sulfanilamide was used because it is much more readily tolerated by children than sulfapyridine and causes less vomiting; it is also cheaper. If there is any vomiting, the lost dose is immediately readministered. Sulfanilamide alone was given to 94 patients, the average daily dose varying from 2.5 Gm. in infancy to 7 Gm. in older children, and the usual period of treatment was ten days. An adequate initial dose was considered to be of paramount importance; at least half of the total daily dose was given as the initial dose. In a few cases sulfapyridine was given alone and in others to alternate with sulfanilamide. Two patients were given serum intrathecally and intramuscularly. Fluids were administered liberally, if necessary parenterally, and an iron mixture was given during convalescence. Complications of sulfanilamide therapy were cyanosis, morbilliform eruptions and sometimes severe anemia. It seems to be the susceptibility of the individual hemopoietic system rather than the amount of the drug administered that determines the onset of anemia. Of 102 patients 13 died, giving a case fatality of 12.7 per cent. Of the 13 who died, only 7 had received adequate therapy. In 54 children under 3 years the fatality rate was 14.8 and in 21 under 1 year it was 19 per cent. The most favorable age group was 5 to 10 years, in which there were no deaths.

Deficiency of Vitamin C and Vitamin P in Man.—According to Scarborough, a low capillary resistance in people with various forms of nutritional deficiency was found to be associated with a deficiency of vitamin P. This communication demonstrates existence of deficiencies of both vitamin C and vitamin P in man. The 6 patients studied all had a clinical deficiency of vitamins but, apart from this, were free from other obvious organic disease, except patient 1, whose blood gave a positive Wassermann reaction. Patients 4, 5 and 6 gave a history of chronic alcoholism. All were in bed in the hospital during the investigation. On admission each patient was immediately submitted to rigid dietary control, the diet being as far as possible free from vitamins A, the B complex, C, D and E. The calorific value of the diet was unrestricted. Vitamin P was administered as an active fraction prepared from oranges. The administration of vitamin P did not arrest the subcutaneous hemorrhages. Two patients (5 and 6) already showing clinical signs of deficiency of vitamins were given the "vitamin free" diet already described and supplements of vitamins A, B₁, C and D in doses sufficient to correct a deficiency of these vitamins. Capillary resistance was determined repeatedly to assess the deficiency of vitamin P. In neither case 5 nor case 6 was there any hematologic abnormality which could explain the spontaneous bleeding. Since a much increased fragility of the capillary walls (low capillary resistance) was determined in both cases, it is concluded that the spontaneous petechial hemorrhages were due to this excessive fragility. The reported experiments show that at least two forms of subcutaneous bleeding may develop as the result of nutritional deficiency in man. One form is due to a deficiency of ascorbic acid and is arrested promptly by the administration of this substance but not of vitamin P. It is not necessarily accompanied by a low capillary resistance, although, since dietary deficiency in the human subject is almost always multiple, it is often associated with a decreased resistance. A decreased capillary resistance is an expression of a deficiency of vitamin P and is increased promptly by the administration of this vitamin but not of ascorbic acid. Spontaneous petechial bleeding may develop when the capillary resistance is low. It is associated with feelings of lassitude and easily induced fatigue and with pains in the shoulders and legs. It is an expression of a deficiency of vitamin P and is controlled by the administration of this vitamin. The two forms of hemorrhage are different in appearance. The hemorrhages characteristic of a deficiency of ascorbic acid are large (ecchymoses) and involve considerable areas of subcutaneous tissue and muscle. The gingival bleeding which develops in scurvy is an expression of a deficiency of vitamin C and is not controlled by the administration of vitamin P. The hemorrhages developing as the result of a deficiency of vitamin P are always small (petechiae) and take place in the skin. They are often circumpilar. Both forms of hemorrhage tend to appear first and are often more severe in parts exposed to the pressure of clothing and in the legs because of the higher venous pressure in that part.

*Thyroid Hormone in Congenital Myxedema. A. Buzzo, A. A. de Muñoz and A. Calabrese.—p. 194.

*Sulfanilamide in Treatment of Fissured Nipples. H. Magliano and H. Ivon Manara.—p. 203.

Thyroid Hormone in Congenital Myxedema.—Buzzo and his collaborators administered thyroid hormone (thyroglobulin) in several cases of typical congenital myxedema of infants. Five cases are reported. The substance was administered in fractional daily doses of from 0.01 to 0.05 Gm., given by mouth for two consecutive weeks, followed by periods of rest of one week for the first year and of two weeks for the second and last year of the treatment. Vitamins A and D were given to the patients from the sixth month of the treatment on. The treatment was well tolerated. It caused irritability and insomnia in a few but was controlled by temporary discontinuation of the treatment. The substance is efficacious, easy of administration, has a favorable selective action on the intestine by which constipation is controlled, and does not injure the cardiovascular apparatus. General symptoms, physical and mental signs improve so as to approach the normal or nearly normal state in the majority of cases. The substance possesses pharmacodynamic action as efficient as that of the total thyroid extract and thyroxine but is more persistent.

Sulfanilamide in Treatment of Fissured Nipples.—Magliano and Ivon Manara employed sulfanilamide in 15 cases of unilateral or bilateral fissured nipples. Sulfamidyl (4-sulfamido-2,4-diamino-azo-benzene-hydrochloride) was administered in fractional doses of 0.32 Gm. twice daily for from three to eight days and in rare cases for twelve days. Pain disappeared within the first twenty-four or seventy-two hours of the treatment. Lactation was uninterrupted in most cases and resumed in the rest. The fissures healed in from six to twelve days, and after the crust had fallen off there were no permanent scars. Neither the mothers nor the infants exhibited toxic symptoms. There were no recurrences. More than half the number of the mothers were observed two months after discontinuance of the treatment. They reported on their ability to continue nursing without inconvenience. The drug had no effect on the quantity of milk secretion, which remained as abundant or as scanty as it was before administration of the drug.

*Star-Shaped Cutaneous Telangiectases in Hepatic Cirrhosis and Its Diagnostic Significance. D. Čičovački.—p. 478.

Accidents in Blood Transfusions After Treatment with Azosulfamide and Uliron (Dimethyl-Disulfanilamide). H. Dibold and G. Kirchhofer.—p. 484.

Cutaneous Telangiectases in Hepatic Cirrhosis.—

Čičovački directs attention to star-shaped cutaneous telangiectases, which were observed in 23 of 41 cases of hepatic cirrhosis. Eppinger was the first one to call attention to these peculiar star-shaped vascular dilatations in patients with hepatic cirrhosis. They are reddish violet, roundish, pinhead to pea-sized spots, which have a central angioma-like elevation, from which delicate, meandering vessels radiate in all directions. Thus the formation has the shape of a star. Microscopic examination discloses that they are greatly dilated capillaries. These vascular dilatations are found only on the upper part of the body. Sites of predilection are the anterior thorax, the forehead, the shoulder, the forearm and the back of the hand. That the development of these star-shaped telangiectases is connected with the hepatic disease is proved by the fact that they increase in number and size with the progress of the cirrhosis. Occasionally some spots disappear and reappear later. That they are star shaped and not longish indicates that they are not the simple capillary dilatations of chronic alcoholism; moreover, they were detected also in cases of cirrhosis in which abuse of alcohol could be definitely excluded. Two factors are of diagnostic importance: First, these star-shaped cutaneous telangiectases appear only in cirrhosis of the liver, not in other hepatic disorders (gallstones, simple icterus and so on). Second, not all cases of hepatic cirrhosis show this symptom. Discussing the pathogenesis of the peculiar vascular dilatation, the author suggests a common con-

stitutional cause for the hepatic cirrhosis as well as for the telangiectases. He directs attention to Chvostek's habitus, which is characterized by hypotrichosis of trunk, axilla and mons pubis, by growth of hair deep into the forehead, dense eyebrows and intense growth of beard, also by incretory changes such as enlargement of the pineal body with missing involution, small thyroid, changes in the hypophysis and atrophy of the sex glands. Persons with this habitus have a tendency to proliferation of the connective tissue not only in the liver but also in the other organs. Chvostek maintained that abuse of alcohol is not the only cause of hepatic cirrhosis, because it cannot always be demonstrated and the liver of some alcoholic persons remains unimpaired. The author observed that the majority of patients with hepatic cirrhosis and the star-shaped telangiectases had Chvostek's habitus, and he gives a detailed description of a case in which hepatic cirrhosis and Dupuytren's contracture developed almost simultaneously. These disorders were familial in that they appeared in father and daughter. The two disorders prove the tendency toward a proliferation of the connective tissue; that is, Chvostek's conception of the connective tissue diathesis of hepatic cirrhosis.

Bronchspirometric Experiments on Human Lung.—Jacobæus and Bruce report bronchspirometric experiments on human subjects in whom tests were made for the ability of one lung to do duty for the other in normal oxygen consumption as well as when one lung was made to breathe nitrogen (95 per cent) or nitrogen plus carbon dioxide (5 per cent). In the first study the dyspnea induced by occlusion of one lung was tolerated without difficulty, the respiring lung increasing its ventilation so as to take over the normal bilateral oxygen intake and carbon dioxide output. Oxygen saturation in the arterial blood sank after the occlusion, because the blood flowing through the blocked lung could not be arterialized. The experiments, however, gave no information on the extent to which the occlusion affected the distribution of the cardiac output to the two lungs. The relative values of the cardiac minute volume obtained tonometrically by estimations of the pulse rate and blood pressure indicated that no increase in the minute volume took place during the occlusion. These occlusion experiments seem to be diagnostically valuable for the indication or contraindication of surgical intervention in pulmonary disease. In the second study, in which nitrogen and carbon dioxide were applied to one lung, no greater discomfort was observed. However, in experiments it was found that considerable dyspnea resulted when enough carbon dioxide was added to the nitrogen of the one lung to prevent the output of carbon dioxide from the lung, but not enough to necessitate abandonment of the experiments. The oxygen consumption during both the nitrogen and the carbon dioxide experiments was about as great as in ordinary bronchspirometry. The fact that as much carbon dioxide was given off from the oxygen-breathing as from the nitrogen-breathing lung demonstrated that the excretion of carbon dioxide can proceed independently of the oxygen intake. The oxygen saturation in the arterial blood fell when one lung breathed nitrogen or nitrogen plus carbon dioxide, because the blood passing through it could not be arterialized. In two experiments, regarded by the author as normative, the calculations pointed to an equal distribution of the blood to the two lungs. The relative values for the minute volume of the heart obtained tonometrically by determinations of the pulse rate and blood pressure indicated that no increase occurred in this volume during nitrogen bronchspirometry or in nitrogen in combination with carbon dioxide.

Book Notices

The Control of Tuberculosis in the United States. By Philip P. Jacobs, Ph.D., Director of Personnel Training and Publications. National Tuberculosis Association, New York. Revised edition. Cloth. Price, \$2. Pp. 387, with 3 illustrations. New York: National Tuberculosis Association, 1940.

In this volume the author has presented the entire subject of the development of tuberculosis control work in the United States. Dr. Jacobs has always recognized the importance of the physician in the solution of the tuberculosis problem, and in many places throughout this volume he emphasizes the physician's part in the program. He quotes Osler's famous last words on the subject of tuberculosis to the effect that the leadership in the battle against this scourge is in the hands of the general practitioner. He states that the general practitioner in medicine is in a key position in relation to diagnosis of tuberculosis and to the initiation of treatment for the patient. He calls attention to how physicians in private practice have allied themselves with special tuberculosis associations and have done so much to control the disease. In his chapter on relations with the medical profession, the final paragraph states that "in the light of the experience presented in this chapter it may be said that, although tuberculosis is essentially a medical problem, the control of the disease, a community task, requires the cooperation of the physician in his professional capacity and as a citizen taxpayer with the other lay citizens of his community who comprise the tuberculosis association." Physicians everywhere are desirous of winning a final victory over tuberculosis as they have done with such diseases as smallpox, typhoid and diphtheria. Every physician who reads this book will find much valuable information which he can use in his daily practice, as well as information which will assist him in taking a greater part in the organized movement to control tuberculosis in the United States.

A Comparative Study of the Seasonal Incidence of Mortality in England and Wales and in the United States of America. By E. Lewis-Fanning. Medical Research Council Special Report Series, No. 239. Paper. Price, 1s. Pp. 69, with 13 illustrations. London: His Majesty's Stationery Office, 1940.

The author has recently made a study of English and American seasonal mortality and presents a number of interesting observations. He has used the annual review of the Registrar General's Office for the English and Welsh material and the annual registration area statistics of the United States census for the period from 1931 to 1938; the crude death rates have been standardized for age though not for sex. He found that it was not necessary to correct for monthly shifts in the stratification of the population. In his analysis of the American material he has treated the New England group of states separately from the whole American area. This might seem proper because the wide range of climatic, racial-social factors involved in the consideration of the entire continental American area by comparison with the relatively compact and more homogeneous New England area does produce flattening of the mortality range.

In view of the fact that the British Isles have the presumptive advantage of a maritime climate by contrast to the more brusque continental climate of the United States, Lewis-Fanning's observation that there is a winter disadvantage and a summer advantage of England and Wales over the New England states is of interest. The disadvantages arise largely from the greater English mortality from bronchitis, influenza, pulmonary tuberculosis and pneumonia. This, as he says in his preface, cannot well be accounted for on a climatic factor alone. If one considers general living conditions, it is most likely based on the fact that heating, housing and clothing are more adequate and food more plentiful for the New England population than for the English group.

Secondly, medical care is better as far as medical service, nursing and hospitalization are concerned, all of which would be particularly effective in reducing mortality and incidentally giving point to the gist of the study, namely that the winter and

spring seasonal disadvantages of England might be overcome with more effective work in the direction of preventive medicine and social hygiene.

Unfortunately statistical analysis itself is inadequate for clear-cut conclusions. Even the basic population in the English-Welsh group by contrast to the New England group is decidedly different. Today the term New England does not connote a common hereditary environmental background. Large intrusions of Mediterranean strains (Italian, Jewish, Portuguese) and of French Canadian and Eastern European types have modified the genophase, and this human material has not yet undergone environmental selection in the new habitat in any degree comparable to the English and Welsh groups.

With these reservations in mind—reservations that Lewis-Fanning clearly recognizes—the study is a valuable contribution and should be useful in emphasizing the significance of environmental factors, climatic and seasonal, social and economic, in the evaluation of disease and mortality.

Advances in New York City's Health: Annual Report of the Department of Health of the City of New York for 1939 with a Review of Developments from 1934-1939. Edited by Sarel Zimand, F. H. LaGuardia, Mayor. John L. Rice, M.D., Commissioner of Health. Boards. Pp. 296, with illustrations. New York, 1940.

A chart showing the "conquest of pestilence in New York City" and the total death rate per thousand of population gives a dramatic introductory summary of the battle against disease for little more than a century. We see peaks made by cholera in 1832, 1849 and 1854. On the latter date the total death rate was 47, and from then on it fell steadily, though somewhat irregularly, to 10 in 1939. Each year has seen the scope of work extended. There was but one health center in 1933; there are thirteen today. New developments in the direction of school health and vital statistics services, supervision of food and drug control, sanitary service, public health nursing and industrial hygiene are suggested. The budget of the health department in the year just ended was \$5,728,489. A total of 5,081,064 services and examinations were given to a population of approximately 7,600,000. The incidence of cases and deaths from diphtheria, typhoid and paratyphoid fever reached an all-time low. Only one death from measles was reported. Scarlet fever deaths were the lowest ever reported. For the first time since 1932 a case of smallpox was reported in the city. This story of things accomplished for the protection of health and of victories gained over disease and death is one which could doubtless be told in many other cities. The large population covered, the wide extent of activities, as well as the exceptionally thorough manner in which the facts are reported, give this metropolitan report distinction.

Das menschliche Knochenmark: Seine Anatomie, Physiologie und Pathologie nach Ergebnissen der Intravitalen Sternalpunktion. Von Dr. med. Karl Bohm, Privatdozent an der medizinischen Fakultät der Universität Zürich. Paper. Price, 37 marks. Pp. 286, with 217 illustrations. Leipzig: Georg Thieme, 1940.

During the past few years there have been several monographs on bone marrow aspiration published in Europe. This monograph is by far the most complete and comprehensive. It is divided into two sections. In the first section the author considers the history of the methods of bone marrow study and then takes up the technique of sternal puncture in detail, giving complete information as to the precise method, the needles used, and illustrations of normal marrow in photomicrographs and colored drawings. Embryogenesis of the various cells are next considered. The anatomy of the blood-forming organs and special cell morphology is taken up in some detail and is beautifully and accurately illustrated with photomicrographs and colored plates. The physiology of the bone marrow is concisely summarized and the regulatory mechanism of cytogenesis is explained. The pathology of the bone marrow is considered under the headings of hypoplasia and hyperplasia. The second section is devoted to disturbances involving the erythroid, myeloid, megakaryocytic and lymphatic tissues. Panmyelophthisis is discussed under a separate heading. The diseases of the bone marrow reticulum are next considered. The final discussions are devoted to malignant tumors of the bone marrow and symptomatic changes in the bone marrow as a result of

various infectious diseases. The monograph is concluded with an exhaustive but carefully selected bibliography including a special list of monographs available on sternal puncture. The illustrations both black and white and colored are superior to anything seen in previous monographs on sternal puncture and are particularly helpful. The text is carefully edited and organized and the subject material is well documented. Hematologists and pathologists will find this monograph a most useful addition to their library.

Synopsis of Materia Medica, Toxicology, and Pharmacology for Students and Practitioners of Medicine. By Forrest Ramon Davison, B.A., M.Sc., Ph.D., Assistant Professor of Pharmacology in the School of Medicine, University of Arkansas, Little Rock. Fabrikoid. Price, \$5. Pp. 633, with 45 illustrations. St. Louis: C. V. Mosby Company, 1940.

Though he has not attempted that reorientation without which there would scarcely seem to be good reason for the production of another textbook in pharmacology, the author of this new work has nevertheless trodden the old road in a surprisingly refreshing manner. The book has much merit: it is inclusive, up to date, sufficiently exhaustive for ordinary textbook purposes and extremely readable. Many of Jackson's fine tracings and colored diagrams are borrowed to enrich its pages. The bibliographic references are numerous and evince the author's wide acquaintance with the literature of his subject. There are a few bad printing errors to be corrected before the work goes to press again. The type is very small, but this disadvantage is certainly outweighed by the small size of the volume and by its low price. Unfortunately, there is not enough of the experimental science of pharmacology and there is too much of therapeutics in the book, but it remains to be seen how serviceable this presentation will be in combination with the wide variety of laboratory courses in pharmacodynamics available in our schools nowadays. This new book fully deserves and will surely have a thorough trial by teachers and students this year.

Preface to Eugenics. By Frederick Osborn, Research Associate in Anthropology, American Museum of Natural History, New York. Cloth. Price, \$2.75. Pp. 312, with 12 illustrations. New York & London: Harper & Brothers, 1940.

An up-to-date knowledge of eugenics is no doubt a necessity for medical men. Although this constitutes "a new responsibility for an already overburdened profession, it is also a new opportunity for service, perhaps one of the greatest that remains after the conquest of the infectious diseases." Today many couples, Osborn points out, undoubtedly restrict the size of their families because of fear that their children may inherit some familial defect. In the present state of knowledge they must act on insufficient grounds, for doctors are not trained to give advice of this sort and there is no one else to whom they can turn. "Only the doctor sees in intimate detail the interplay of environment and heredity in which disease and defect may develop, and therefore he alone is qualified to diagnose and interpret the results." The problems which these factors present are by no means academic in nature. Even with our present limited knowledge and with the rudimentary methods available, Osborn estimates that the number of feeble-minded could be reduced by 150,000 a generation for several generations and the number of the schizophrenic and the manic depressive by possibly a like amount.

In order to see the picture in its entirety it is essential to have a working knowledge of the facts of heredity—the known hereditary defects and their mechanism of transmission, the behavior of the genes and chromosomes, the present trends of population both quantitatively and qualitatively, and the eugenic objectives which may be considered reasonable in the light of proved scientific knowledge. In discussing each of these questions Osborn has done a remarkable job of condensation and selection from the vast amount of modern information available. The book is well written and lacking in technical detail, which might interfere with its ease of use. The orientation of the eugenic movement in the light of social policies, nutrition, housing, medical care, recreation and research should be matters of general knowledge. The responsibility of facing these problems is tremendous but "to such a call the doctor has never failed to respond."

Obstetrics in General Practice. By J. P. Greenhill, B.S. M.D., F.A.C.S. Professor of Obstetrics and Gynecology, Loyola University Medical School, Chicago. Cloth. Price, \$3.50. Pp. 448, with 112 illustrations. Chicago: Year Book Publishers, Inc., 1940.

This intensely practical volume reviews in succinct form the knowledge which every safe practitioner of obstetrics must possess. By eliminating historical data, controversial matters and theory, the author has encompassed in a small book the salient facts of everyday clinical obstetrics. Chief attention is devoted to diagnosis, indications and contraindications for operation, prognosis and treatment. The sections on therapy are sound and are presented in such specific detail that they should be of real benefit to the general practitioner. The volume incorporates, moreover, all the more important recent advances; it discusses, for example, roentgen pelvimetry and placentography, sulfanilamide in puerperal infection and the new classification of the toxemias of pregnancy sponsored by the American Committee on Maternal Health. The little chapter on circumcision, a topic not often touched on in obstetric works, should prove most welcome. In sum, Dr. Greenhill's volume can be recommended to general practitioners of obstetrics as a valuable postgraduate course in the "diurnalia" of obstetrics. The format is attractive and the illustrations are well chosen and informative.

Dog-Team Doctor: The Story of Dr. Romig. By Eva Greenslit Anderson, Ph.D. Cloth. Price, \$2.75. Pp. 298, with 21 illustrations. Caldwell, Idaho: Caxton Printers, Ltd., 1940.

The Moravian church sponsored the medical training of young Joseph Herman Romig, who was to dedicate his life to the welfare of the Eskimos in Alaska. Forty-four years ago he went there with his bride and a promise of an expense account of \$50 a year, but no salary for seven years. They were virtually alone in administering to the medical needs of the people of southwestern Alaska for years. There were remnants of Russian occupancy, trappers and adventurers from all corners of the earth when he arrived in this bleak land. Through the days of the Klondike gold rush, days when river traffic grew to hundreds of craft, days of building of railroads and highways and the development of the fishing industry to the present, when the airplane has conquered these wide spaces, Dr. Romig has seen and shared in them all. He has been not only a medical missionary but a superintendent of schools, mayor of Anchorage, a railroad surgeon, a United States commissioner and an expert with a dog team which carried him hundreds of miles over the snow to administer to the sick. This story of his life work reads almost like fiction. Now a modern hospital has been built in Anchorage and the practice of medicine is much simpler. Dr. Romig is living retired at Anchorage, Alaska, but his son is practicing medicine there.

Test Tubes and Dragon Scales. By George C. Basil, M.D. In collaboration with Elizabeth Foreman Lewis. Cloth. Price, \$2.50. Pp. 316, with illustrations. Chicago, Philadelphia & Toronto: John C. Winston Company, 1940.

This book relates numerous incidents that occurred in China when a young American physician went to Chungking to become busily engaged in medical work in an American founded hospital. Chungking, now the capital of China, was founded about 2200 B. C. This prosperous port at the confluence of two rivers clung to its ancient pattern of existence until a short time ago, when war forced the removal of China's capital back into the deep interior. When Dr. Basil left Chungking in 1932 the city was almost the same as it had been centuries before. His patients had been mostly poor Chinese, but some of them were generals, politicians and communists, as Chungking formerly was the center for the Chinese Communist army, which later threw all its strength into the defense of China against a foreign aggressor. This experience gave the author opportunity to look into the ancient Chinese pharmacopeia and medical practice and to get occasional glimpses into the military and political life of this then hoary Chinese community. Dr. Basil was born in 1902 and graduated from the University of Maryland School of Medicine, Baltimore, in 1927. He now practices medicine in Annapolis, Md.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CHRONIC RESPIRATORY INFECTION AND CLIMATE

To the Editor:—Two patients, mother and daughter (about 8 years of age), are both subject to continual colds during the winter months. The condition in each one takes the form of a catarrhal infection of the upper respiratory passages and has resisted the usual remedial treatments. They live in the mid Hudson valley, where fogs and dampness are prevalent. The husband is a fruit tree expert and as a change of climate is being considered he will be obliged to select the region for his family's residence accordingly. Can you point out to me the regions in the New England and Middle Atlantic states that have a drier climate? I have heard it said that Maine is a good state for cases of this kind.

M.D., New York.

ANSWER.—Migration for well established catarrhal states of the upper respiratory passages is scarcely worth considering unless it can be to the nonstormy regions of the Southwest. The frequency and severity of sudden storm changes in the weather seem to be an important causative factor in the genesis of respiratory infections and in the maintenance of such troubles once they have become chronically established. There is no nonstormy region in the northeastern part of the United States. Maps showing the courses followed by storm areas in their passage across the continent have recently been published (Mills, C. A.: Medical Climatology, Springfield, Ill., Charles C. Thomas, 1939) and on these maps it is seen that any migration to avoid storm effects must be to the Southwest. New Mexico, Arizona and southern California offer the only regions free from winter storminess. Fortunately for the family in question, that region has a considerable fruit-growing industry. Since the query referred only to migrational possibilities, no other phases of the handling of nasal catarrh are considered in this reply.

PREECLAMPTIC EDEMA

To the Editors:—Ammonium chloride and ammonium nitrate have been successfully employed in the management of edema, particularly that of cardiac origin. In preeclampsia, however, it seems that the mechanism of edema formation is not well understood; furthermore, one of the basic objectives of most treatment routines is the prevention of acidosis. Is the use of these drugs in the management of preeclamptic edema (unaccompanied by frank acidosis) (a) permissible, (b) rational, (c) effective? Are mercurial diuretics indicated?

M.D., Illinois.

ANSWER.—It is quite true that the mechanism of preeclamptic edema is not solved. It is obviously not cardiac in origin and not attributable primarily to albuminuria and hypoproteinemia. Presumably, some endocrine disturbance may be the chief factor in view of the striking effects of the estrogens and adrenal cortex extract on water and salt balance. Whether these substances act on the renal tubule alone or on the tissues in general is not established. In either case the treatment of preeclamptic edema involves the same general principles as other types of edema—rest, restriction of salt and water, and the use of diuretics. Since there is no significant acidosis in preeclampsia, ammonium salts may be given and will be effective provided the patient can tolerate them. Gastrointestinal irritation may limit their usefulness. Mercurial diuretics are not contraindicated if renal function is satisfactory. For some unknown reason, however, little diuresis ordinarily results. This fact perhaps supports the theory of the renal site of action of the edema producing mechanism.

INSPECTION OF CONJUNCTIVA

To the Editor:—Please outline for me the known methods of inspecting the upper angle of the conjunctiva.

E. R. Hargett, M.D., Springfield, Ohio.

ANSWER.—The methods of inspecting the upper angle of the conjunctiva, by which is undoubtedly meant the conjunctiva lying in the cul-de-sac formed by the upper lid at the upper rim of the orbit, where it approximates the globe are: 1. According to the description in Gifford's textbook "This may be done while facing the patient, if the head is supported by a headrest. For convenience in using ordinary chairs, it is best to stand behind the patient with the head resting against one's body. The patient is asked to look down. With the thumb and forefinger of the right hand, the eyelashes of the upper eyelid are grasped and the lid is pulled downward and away from the globe. The

forefinger of the left hand is now used to press against the upper edge of the tarsus, through the skin, while the right hand pulls the eyelid quickly upward over the left forefinger as it holds the tarsus. The left hand is now removed and the lash border is held against the upper orbital rim while the tarsal conjunctiva is examined. An applicator or tooth pick may be used to replace the left forefinger, but it is less convenient as it requires to be held in place, while, when the eversion is completed as described the left hand remains free and for necessary manipulations and treatments."

2. A hand lid evorter may be purchased from any surgical or optical supply house. The evorter has a flange by means of which the entire upper lid is spread out and the cul-de-sac readily exposed.

3. Frequently, an ordinary lid clasp forced as far back as possible on the lid and then causing an eversion of the lid will readily expose the angle of the conjunctiva.

It is absolutely necessary that the eyeball be directed downward, as this pull on the bulbar conjunctiva adds in spreading out the loose conjunctiva of the upper angle where it meets the palpebral portion.

NUMBNESS OF FACE AND MIGRAINE

To the Editor:—For several months I have been giving ergotamine tartrate (gynergen) for migraine headaches. I give 0.5 cc. (0.25 mg.) at the beginning of the menstrual period, at which time the headache begins, and get relief inside an hour, which headache does not return till the next period. No other treatment is of any avail. The most recent headache was just treated in the same way. The patient states that from two weeks ago till now she has had a constant feeling of slight numbness and tingling of the left side of the face. Isn't it possible that the ergotamine tartrate is not the causative agent of her symptoms, owing to the fact that toxicity generally shows by these symptoms in the extremities rather than in the face, that these symptoms are really noticeable only when the patient is nervous (which is often), that the effective dose is small and not repeated for a month, that her symptoms started two weeks after the last dose, that the patient is slightly anemic and that she is conscious of herself and intelligent and likely to have found out the possible toxic effect? What would you advise?

S. J. Hyman, M.D., Inkster, Mich.

ANSWER.—The symptoms described following treatment with ergotamine tartrate for migraine headache suggest a neurosis or possibly a vascular lesion of the posterior fossa. With respect to the latter, it would be wise to obtain a careful examination of the cranial nerve and other central nervous system function. X-ray films of the skull and lumbar puncture are indicated. Such pathologic change might be in the nature of an aneurysm (which could account for the headache) or a tumor in the pontile angle or, finally, a vascular lesion in the medulla, which in turn might or might not be due to vasoconstriction following ergotamine therapy. It is unlikely that ergotamine tartrate is the cause of the patient's symptoms. It is likely that they are psychogenic but it is more probable that they have recently become a part of the migraine syndrome itself. Occasionally a mixture of trigeminal and migraine symptoms occurs in the same patient. Their constancy, however, suggests a possible vascular lesion. It would be wise to omit the treatment until all aspects of the problem have been thoroughly studied.

An attempt might be made to control the headache by inhalation of 100 per cent oxygen at 7 liters per minute for an hour to two hours, thus giving one a chance to study the facial paresthesias in the absence of ergot therapy. The use of vitamin B complex might lessen the paresthesia.

POLLEN AS CAUSE OF ASTHMA WITHOUT HAY FEVER

To the Editor:—Several patients with asthma react severely to ragweed pollen extract in the scratch test. They do not appear to have symptoms of hay fever, but all have asthma at various times of the year and also during the early fall when the ragweed season is on. While the other reaction gives some clues to the asthmatic attacks from various sources, the question arises whether these patients need protection from ragweed pollen. In other words, does ragweed pollen cause bronchial asthma in some persons and hay fever in others? As I have observed a strong reaction of this sort in a large number of cases, the solution of this problem is quite important.

Paul Lahvis, M.D., Gowanda, N. Y.

ANSWER.—Ragweed pollen and other pollen not infrequently are the cause of asthma in the absence of hay fever. In many such instances the hay fever has been present earlier in the career of the patient's allergy; in others, nasal symptoms have never manifested themselves. This situation should not be surprising in view of the fact that asthma is not uncommonly caused by other inhalants in the absence of rhinitis. In the conditions described in the question, some additional observations might be significant in reaching a decision. Does the asthmatic patient consider autumn one of his bad periods? Did he, at the beginning of his asthma career, have fall asthma

QUERIES AND MINOR NOTES

660

as his initial allergic experience? Even if these questions are answered in the negative, it is still possible that ragweed pollen may be an etiologic factor. A test which might help is the insufflation of a moderate quantity of the dry pollen. An asthmatic attack following would lend strength to the belief in this antigen as a significant cause; a negative result, however, would not disprove that possibility. It is important, of course, to remember that a violent and prolonged attack may result from such a procedure. In case of any doubt, the stand should be taken that the safer and wiser course to follow is to treat such patients with pollen extracts rather than to fail to do so because of some degree of uncertainty of the etiologic role assumed by the pollen.

RECURRENT CARBUNCLES

To the Editor:—A patient with recurrent carbuncles about the neck and back has tried many treatments for five years without success. Please give me a suggested dosage of sulfathiazole for such a condition. How long a time should medication be continued? The patient is 17 years old. M.D., Massachusetts.

ANSWER.—In recurrent furunculosis and carbuncles the following treatment may be attempted: Staphylococcus toxoid may be administered in order to prevent the development of new lesions. Full strength staphylococcus toxoid (containing 1,000 units of toxin per cubic centimeter) may be given subcutaneously. The first dose would be 0.02 cc., with subsequent doses of 0.04 cc., 0.07 cc., 0.10 cc., 0.15 cc., and 0.20 cc. at intervals of four days. Local erythema may be noted at the site of injection, and sometimes fever occurs. In addition, in the acute phase in an adult, one can administer sulfathiazole, giving an initial dose of 4 Gm., followed by 1 Gm. every four hours until definite improvement is noticed, at which time the dose may be cut to 1 Gm. four times a day, this to be kept up until the infection is completely under control. Frequent hot saline compresses or fomentations should be applied to the local lesion. Incision should be employed after definite fluctuation develops in order to evacuate the pus and necrotic material. Great care must be taken to avoid the incision of uninfected tissue and of tissue with nonfluctuant cellulitis.

PROSTIGMINE METHYLSULFATE TEST FOR PREGNANCY

To the Editor:—A pamphlet on the use of prostigmine methylsulfate as a test for pregnancy states that if used as described it is a safe, reliable and accurate test for pregnancy, having the same degree of accuracy as the Friedman test. I am interested in this test and would appreciate any comment, especially as to its safety in pregnancy and its accuracy. T. T. Rackliffe, M.D., Los Angeles.

ANSWER.—In an article published by Soskin, Wachtel and Hechter in THE JOURNAL May 25, 1940 on the treatment of delayed menstruation with prostigmine methylsulfate it was concluded that prostigmine methylsulfate had no effect on early or prolonged amenorrhea due to endocrine dysfunction or to local organic changes. Also, experimenting on animals and man, these authors conclusively demonstrated that prostigmine methylsulfate does not initiate menstrual flow when the delay is caused by pregnancy. On the basis of constancy of the results on pregnancy (i. e. absence of bleeding) they concluded that it is a therapeutic test for pregnancy.

Since they injected 2 cc. of a 1:2,000 solution of prostigmine methylsulfate on two or three successive mornings in twenty-three known pregnant women without causing a disturbance in the pregnancy, it seems that the test is a safe one. However, since they claim that the test is not entirely reliable in endocrine disturbances, menopause and local conditions, procedures necessary to rule out these exceptions are of such magnitude as to make the test far inferior to the Friedman or the Aschheim-Zondek test. In the Friedman or the Aschheim-Zondek test a negative reaction rules out the possibility of pregnancy in at least 98 per cent of the cases. A communication in the correspondence column of THE JOURNAL Dec. 14, 1940, page 2103 reports the test ineffective in 4 cases.

ECHINOCOCCUS INFECTION OF LIVER

To the Editor:—Please let me know what is the modern acceptable treatment for echinococcus infection of the liver. M.D., New Jersey.

ANSWER.—The best treatment of echinococcus infection of the liver is prophylaxis. This should consist of avoiding, as far as possible, intimate companionship with dogs. Persons should wash their hands thoroughly after handling dogs. Foods should be thoroughly cleaned and washed before eating. Care should be taken that drinking water has not become con-

Many drugs have been tried in the treatment of this disease. Some favorable results have been reported in individual cases, but the number of patients who have been treated with any one drug is not sufficient to warrant the recommendation of the drug. There is no specific drug for the treatment of echinococcus infection of the liver. As far as is known, none of the newer drugs such as the sulfamido compounds have been used successfully in the treatment of this infection. It is believed that these drugs would not be efficacious in the treatment of parasitic infections. A former mode of treatment, such as aspirating the cyst, has been largely discarded because of the danger and because of the hazard of spreading the infection. The injection of certain antiseptic substances such as phenol, alcohol, iodine and solution of formaldehyde has largely been discarded.

If the parasite dies and the cyst becomes calcified, no treatment is indicated. If the cysts become large and troublesome they should be excised. If they become suppurative they should be incised and drained.

COHESION BETWEEN VISCERAL AND PARIETAL PLEURA

To the Editor:—Normally one defines negative intrathoracic pressure as the difference between the pull of the elastic tissue in the lungs to collapse them and the intrapulmonic pressure which holds the visceral pleura in contact with the parietal at all times. The question arose as follows: A patient developed pleurisy and it was discovered that the visceral pleura of the entire right upper lobe of the lung became adherent to the parietal pressure, thus obliterating the potential space responsible for the negative pleura had the patient not developed pleurisy in that particular area. Is negative pressure still present in the area when the entire visceral pleura has become adherent to the parietal pleura, assuming that the right middle and lower lobes and pleura are still normal? Are the forces defined under negative pressure normally still present when one develops a pleurisy and as a result the pleurae become adherent? M.D., N. Y.

ANSWER.—To speak precisely, there is no negative pressure in the pleural cavity because under normal conditions there is no pleural cavity. The retractile force of the stretched lungs is exerted against the cohesive force between the visceral and parietal layers of the pleura. When these two layers have become adherent, the force is still exerted in the same direction. Instead of being exerted against the cohesion of the two layers, it is now exerted through the adhesions and so, as under normal conditions, is transmitted to the ribs, intercostal tissue and even the overlying muscles, fat and skin, as is evidenced in thin persons by the retraction of the intercostal spaces on deep breathing. This retraction occurs whether or not there are adhesions.

RAPID DEVELOPMENT OF UTERINE FIBROMYOMAS

To the Editor:—Please let me know whether it is possible for a fibroid tumor of the uterus the size of a three months pregnancy to grow within a period of three months. The patient was operated on and a fibroma of the uterus was removed. The symptoms of bleeding existed only during and following the last period two weeks before operation and there were no other symptoms previously. Have any fibroids at any time been known or recorded anywhere that have grown so rapidly in so short a time? M.D., New York.

ANSWER.—It is possible for a fibroid tumor, not palpable on examination by a skilled gynecologist, to develop to the size of a three months pregnant uterus within a period of three months. This statement should not be made without explanation. In most instances the supposedly rapid increase in size is ascribable to failure to recognize the true size of the growth at the time of the preliminary examination. Nearly all tumors which have really developed rapidly reveal evidence of excessive vascularity, hemorrhage into the tumor, necrosis with infection or malignant degeneration. Pure myomas also develop rapidly in a moderate percentage of cases, in contrast with firmer fibrous or fibromyomatous growths.

ESTROGENIC SUBSTANCE AND MIGRAINE IN MEN

To the Editor:—Some of my colleagues have been using injections of estrogenic substance to prevent or delay attacks of headache and nausea in women suffering from migraine. I have used it to a limited extent with encouraging results in women. A man aged 26 has suffered from fairly typical migraine since childhood. I wish to ask your advice on the use of estrogenic substance or some comparable substance for the control of migraine in men. Edward Bloir, M.D., Healdsburg, Calif.

ANSWER.—Although there are many favorable reports concerning the use of estrogenic substance for women suffering from migraine, several years' observation of this type of treatment has in other hands shown rather questionable results. So far as known, such type of treatment has not as yet been used for men.

SOME WAR ASPECTS OF MEDICINE

REPORT OF THE CHAIRMAN OF THE COUNCIL ON
MEDICAL EDUCATION AND HOSPITALS

RAY LYMAN WILBUR, M.D.,

STANFORD UNIVERSITY, CALIF.

Minorities' sponsoring causes in which they believe make most of the policies of democracies. The doctor believing in himself and in medical work has through his organizations interested himself in medical education in order to give assurance that those who care for the sick know their business. One of the striking chapters in the history of education covers the part played by the American Medical Association in influencing the development of sound medical education in the United States. If the public had had to wait for conditions to develop so that a majority would interest itself in seeing that good medical schools were provided, we would have but few of these schools today. It was the understanding of the physician and his willingness to take the responsibility and to do the work that has made possible this Council with its influence on medical education and hospitals.

Over the last few decades every one will admit that there has been a steady improvement in medical schools, in the kind of training received by the doctor, in the hospital training of the young physician and in the hospitals themselves.

During the past year the activities of the Council have been along the usual lines. We can report that most of the medical schools have made substantial recovery from the difficulties in which they found themselves as a result of the depression. All of them are handicapped, as are the universities and research institutions, by the declining income that has resulted from the lowered interest rates which are now prevailing. Even though the processes of medical education have become more expensive, owing to the increase in the facilities required for modern medical training, there has been sufficient financial support to keep abreast of the best in medical education as far as the majority of our institutions is concerned.

The reports received from a large number of medical schools and follow-up inspections of others indicate that, as a result of the Council's survey during 1934-1936, substantial improvements have been and are being made. Where facilities have been inadequate the size of classes has been reduced, entrance requirements have been raised in a certain group of institutions, the teacher-student ratio in the basic medical science depart-

ments is now 1:8 as compared to 1:11 in 1934, clinical facilities have been improved, budgets have increased, and curriculums have been revised.

The Council has undertaken a program of cooperation with the various specialty boards looking toward the establishment of uniform standards in the field of graduate medical education and the elimination of unnecessary duplication in the inspection of hospitals which undertake to train residents in the various specialties. Negotiations have already been completed or are under way with thirteen boards. Official information is secured from hospitals on forms printed in triplicate so that one copy may be retained by the institution, one copy by the Council and one by the special examining board concerned. The actual inspection of the hospitals is carried out by members of the Council's staff. Copies of the reports of these inspections are likewise transmitted to the examining boards. It is expected that in the final evaluation of residencies and fellowships the conclusions of the Council and of the boards will be identical, so that it may be said that any institution approved by the Council will be equally acceptable to the specialty boards.

Conferences have been held between the Trustees of the American Medical Association and the Board of Regents of the American College of Surgeons, and also between members of the staff of the Council on Medical Education and Hospitals and the administrative staff of the College of Surgeons. These conferences have resulted in closer cooperation and collaboration in the collection and publication of hospital statistics.

According to the latest figures compiled there are 6,226 hospitals registered by the Council, having a bed capacity of 1,195,026 and 58,764 bassinets, 9,879,244 admissions and an average daily census of 996,483. Of these 736, with 7,998 internships, are approved for this training, and 555 are approved for 4,709 residencies. In addition, the Council lists 154 schools of laboratory technic, 16 schools offering courses in physical therapy, and 6 schools of occupational therapy, all of which are approved by the Council.

Since the first classification of medical schools and the publication of the Carnegie report there has been probably no five year period which has witnessed such activity and progress in the field of medical education.

Medical licensure statistics published in 1940 revealed that 6,043 physicians were licensed (for the first time) to practice medicine. Here is no indication of a dearth of doctors. Quality, however, is more important than quantity, and in this respect the situation is less satisfactory. One hundred and ninety-five graduates of unapproved schools were admitted to practice in thirteen states. A still more serious degradation of the standards of medical practice results from the trend in recent years to abolish the restrictions which have heretofore

WAR ASPECTS OF MEDICINE—WILBUR

662

governed the practice of osteopathy. In seven states medical licenses have been issued to 118 osteopaths who are not graduates of any medical school. During the year also 925 licenses have been issued to graduates of foreign faculties of medicine.

A revision of the "Principles Regarding Graduate Medical Schools" was ratified by the House of Delegates in June.

RESPONSIBILITIES OF THE COUNCIL

Acting on the request of the Reference Committee on Medical Education of the House of Delegates last June, the following resolution was presented and approved, clearly indicating to the public and to the medical profession the responsibilities of the Council in the field of medical education and the channels through which these responsibilities are to be discharged:

WHEREAS, When the American Medical Association was organized in 1847 the following statement was contained in the Plan of Organization: "Inasmuch as an institution so conducted as to give frequent, united, and emphatic expression to the views and aims of the Medical Profession in this country must at all times have a beneficial influence and supply more efficient means than have hitherto been available here for cultivating and advancing medical knowledge, for elevating the standard of medical education, for promoting the usefulness, honor, and interests of the Medical Profession, for enlightening and directing public opinion in regard to the duties, responsibilities and requirements of medical men, for exciting and encouraging emulation and concert of action in the profession, and for facilitating and fostering friendly intercourse between those who are engaged in it"; and

WHEREAS, In successive years the Committee on Education reported on existing conditions and made recommendations for the sound development of medical education in this country; and

WHEREAS, Immediately after the reorganization of the American Medical Association in 1902 more active measures were taken to examine and appraise the existing facilities for the training of physicians, leading, in 1904, to the establishment of the Council on Medical Education as a standing committee of the House of Delegates; and

WHEREAS, The Council conducted the first comprehensive survey of medical schools that was ever made and later secured the assistance of the Carnegie Foundation for the Advancement of Teaching, which sponsored the extraordinarily influential Flexner report; and

WHEREAS, Over a period of thirty-five years the Council on Medical Education and Hospitals has, through its inspections, reports, and published classifications, steadily raised the standards of medical education and practice; and

WHEREAS, Throughout the period of its existence the Council has sought attainment of objectives equally beneficial to the medical schools, the hospitals, the interns, the medical profession and the public; therefore be it

Resolved, That the House of Delegates reaffirms its approval of the activities of the Council; and be it further

Resolved, That the Council is hereby directed to continue to discharge those functions outlined in chapter IX, section II, of the By-Laws, namely (1) to investigate conditions of medical education including premedical, undergraduate and graduate medical education, hospitals and associated subjects and to suggest means and methods by which the same may be improved; (2) to endeavor to further the realization of such suggestions as may be approved by the House of Delegates.

The faculties of medical schools have been classified with respect to availability for medical service. An alphabetical list is now in the possession of the Surgeon General of the Army and the surgeon of each corps

The Council has now in process of preparation part II of the Council's study of graduate medical education in the United States. This volume will deal with institutional apprenticeships; namely, internships, residencies and fellowships.

NEW CONDITIONS TO BE FACED

We now face an entirely new set of conditions. With the various emergencies and the changes that they have brought about in finances, as well as all sort of controls, and with compulsory military training under the Selective Service Act of Oct. 16, 1940, we are in the midst of forces that may bring harm to all that has been built up through the past five decades unless great care is taken.

Under the Selective Service regulations, except for the current year, there is no exemption provided for medical students, nor have we protection in the law for instructors, residents, interns, hospital staffs and faculties of medical schools. What happens to them depends on the gambling chances of a numbered Selective Service and the wisdom or lack of wisdom of the draft boards. Because of inattention or for some other reason we have neglected to give the protection to medicine that was found requisite through our own experience during the last World War and that has been generally accepted by belligerents in the present war as a sign of reasonable common sense.

It would seem about time that those who believe in what medicine can do and in its destiny should again take hold of the situation and give the public and the soldiers the protections that in a long war can come to them only by maintaining our student bodies in the medical schools, our faculties of medicine and our staffs in the hospitals. There should be no element of chance in this matter. We should do what we have to do with devotion to the requirements of our country in time of strain; but we as medical men should have the voice as to what is important to protect in medical institutions and in the maintenance of our medical institutions.

Certainly the medical care given a modern army is of the utmost importance. We need only remember that a century and a half ago those European armies that had organized and efficient medical care were able to keep their fighting forces available for action with less human wastage than their opponents. From that time on the doctor began to count in offensive military programs. With the development of modern medical science the trained physician has become indispensable in military affairs, not only in the care of the wounded and sick, but also from the standpoint of prevention of disease and for the selection of those men capable of the strain of military life.

So indispensable has become the doctor that now when we speak of bringing a hundred thousand men into military service we take it for granted that a certain percentage of these men will be trained physicians and others connected with medical and hospital services. The European nations now find under the exigencies of so-called total war that the care of the civilian population must be guided to a considerable extent by the men of medicine. The dislocation of large groups in the population, the spread of diseases associated with deprivations of food and with famine, and the spread of contagious diseases all require the expert in the laboratory as well as in the clinic and the hospital.

Our country is well entered on a great mass operation of defense. This extends certain of our activities and limits others, but in no way does it change the essential fact that the defense of a great democracy will require as many, if not more, thoroughly trained medical men as in the times of peace. While we can drain off a certain number of our active practitioners into the service of the army, navy and public health, we cannot diminish the numbers taking medical training, nor can we speed up that training beyond a certain point without obtaining an unsatisfactory result.

In other words, the present crisis demands more and better and more up-to-date medical students if we are to face the future with equanimity and without undue concern. We know from long experience that the process of selecting young men and women each year to be recruited by our medical schools is not a simple one. Only a certain percentage of our young people are fitted by temperament, intellectual capacity and physique to take up the arduous study of medicine. We must guard against having them diverted into some form of required military service so that they are lost to medicine. If those in authority in this country are wise they will make provisions through legislation so that no medical student can be drafted or volunteer, and so that those who are proposing to study medicine are given adequate trial before they are drafted into some other line of duty. After the first hospital year (which is really a part of medical education) is completed then the young physician can be relieved for such military or civilian service as seems most appropriate for his qualifications or as most needed. It will be difficult to maintain the further training in the hospital which is required for those who are to be specialists; but provisions for this should be made and authority given to those who head our medical institutions to save from the waste of ordinary military service those who show special skill in either the laboratory or the clinic. It may be that the best procedure would be for them to be drafted and then sent back to the medical institutions or hospitals concerned.

For years we have talked about preventive medicine. We have built up our whole scheme of medical practice in relationship with the public health authorities, so that prevention is a part of the everyday practice of medicine. Now that we face the need of bringing the doctor into the best possible relationship to a future that is yet undetermined but is sure to need the skill of a large number of trained men, we should do as we do in preventive medicine and think of the future and not burn out our material because of some preconception or red tape or false idea of what democracy means. Democracy does not mean that we are equal or alike in capacities or interests. It means only that we should be equal in opportunity and in freedom. We must not confuse political equality with equal capacity to do the things that a diversified civilization requires. Democracy can succeed only if it trains those who are to be leaders and accepts their guidance.

We who represent medical schools and medical institutions should take the active responsibility of seeing that medical institutions are not hampered or destroyed or even materially handicapped. We must see that they are kept at their task of preparing as large a number of well trained men and women in the field of medicine as physical and clinical facilities permit.

HUMAN EXPERIMENTAL SCURVY AND THE RELATION OF VITAMIN C DEFICIENCY TO POSTOPERATIVE PNEUMONIA AND TO WOUND HEALING

CHARLES C. LUND, M.D.
AND
JOHN H. CRANDON, M.D.
BOSTON

Since Lanman and Ingalls¹ demonstrated that vitamin C deficiency led to poor healing of experimental surgical wounds in guinea pigs and after operations on children there has been an increasing recognition by other surgeons (Wolfer² and Holman³) as well as by Lanman that this factor may be of importance in surgical operations on adults. Since vitamin C was isolated by Svirbely and Szent-Györgyi⁴ and synthesized by Reichstein and his co-workers⁵ there have been many tests for vitamin C developed for the determination of its content in foods, tissues, urine and blood. It is now realized that certain of the older methods of analysis did not give accurate results, but it is hoped that present methods will be of value within certain rather broad limits.

At the time this study was begun two and one-half years ago little was known concerning the vitamin C status of surgical patients, although Ingalls and Warren⁶ indicated that most patients under medical treatment for gastric and duodenal ulcer had very low levels of the vitamin in the blood plasma. The present study has been focused particularly on the determination of the presence and degree of, or the absence of, vitamin C deficiency among patients of all types coming into surgical wards, and on determining any differences in any aspects of the surgical convalescence of patients according to the deficiency found. It was early found that complementary studies on normal persons were necessary in order to interpret the conditions found in patients.

A paper has been published by one of us⁷ showing that the reduced vitamin C level in the plasma drops markedly immediately after operation but that the patients who show this drop have no clinical signs of scurvy even if the plasma level reaches zero. Several normal persons were put on a diet totally deficient

Read before the Section on Surgery, General and Abdominal, at the Ninety-First Annual Session of the American Medical Association, New York, June 12, 1940.

Dr. Allan Butler and Miss Margaret Cushman performed whole blood and white cell platelet determinations and gave technical advice; Dr. Frederic Parker Jr. and Dr. Kenneth Mallory reviewed the biopsy specimens.

From the Department of Surgery, Harvard Medical School, and the Fifth Surgical Service and the Surgical Research Laboratory, Boston City Hospital. This work was aided by grants from the Wellington Fund of the Harvard Medical School and from several anonymous donors. Assistance in securing the data was furnished by the personnel of the Works Progress Administration (projects 14667, 17580 and 21502).

in vitamin C for periods extending up to three weeks. In all these persons the drop was rapid and reached very low levels.

It was known as a result of Emmerie and van Eekelen's⁸ work that a normal person with a maxi-

Last fall the work had progressed to the point at which it seemed to be important to carry out further experiments on the development of human scurvy in the normal person. For this purpose one of us (J. H. C.) went on a scurvy-producing diet on Oct. 19, 1939 and remained on it until May 7, 1940. The diet was supplemented with adequate but not excessive doses of vitamins A, D, E and B complex. A report of this experiment has been published.¹³ Three months after the diet was started a 2½ inch (6 cm.) experimental wound was made down through the deep fascia of the lumbar region and a specimen was secured for biopsy in eleven days. No defect in wound healing could be demonstrated on pathologic examination.

Shortly after five months the first sign of scurvy developed (in this instance petechial hemorrhages around the hair follicles of the legs). But three weeks before this hyperkeratotic papules had developed on the buttocks. These contained ingrowing hairs and simulated the lesions associated with vitamin A deficiency. Although there was slight lassitude and ease of fatigue in the fourth and fifth months, marked fatigability began only in the sixth month. No ecchymoses occurred and no changes of the gums.

At exactly six months a second incision was made in the corresponding position in the other side of the back. It was found almost impossible to suture the transversely divided sacrospinalis fascia because the sutures stripped out between the longitudinal fibers, a difficulty which had not presented itself three months

□, X, △, ○ — Each represents a different man

Fig. 1.—Plasma ascorbic acid levels of 4 normal men on a scorbutic diet.

mum storage of vitamin C would not get scurvy as a result of a diet totally deficient in the vitamin in eighty-four days, but they believed that the person studied was close to having scurvy at the end of the experiment.⁹ Van Eekelen followed the urinary output and whole blood level of ascorbic acid during this dietary experiment and found that the urinary output dropped to low levels as soon as the patient started the diet but that the level in the blood fell gradually in a straight line at the end of the experiment. Van Eekelen used a method for determination of the vitamin in the whole blood that is difficult, and we have been unable to use it in spite of three months' constant effort in the laboratory.

The work reported here was done by Pijoan and Klemperer's¹⁰ method at the start and later by Mindlin and Butler's¹¹ macromethod. The difference in the two methods lies essentially in the use of cyanide in the former. Cushman and Butler¹² have shown that cyanide does no harm (if a proper cyanide is used) but also that it does no good. Most of our determinations were made on blood plasma, except a few determinations of the white cells in our most recent work.

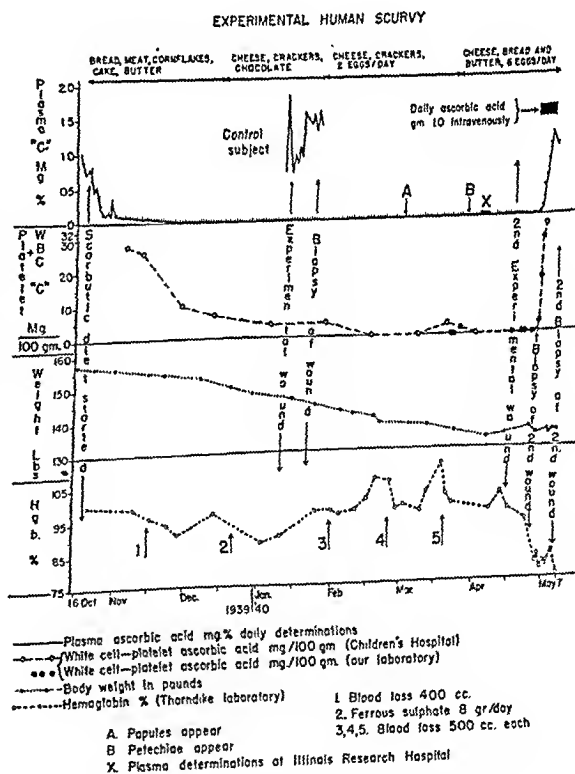

Fig. 2.—Blood chemistry and diet in human experimental scurvy.

earlier. Finally four silk sutures were applied and tied on each side and then brought together and tied in the way tendon sutures are made. There was no difficulty with the latissimus fascia which had been longitudinally

divided. This was brought together with a continuous suture. The skin was brought together with interrupted silk sutures.

This wound seemed to heal by first intention. The cutaneous sutures were removed on the sixth day and

Fig. 3.—Normal healing at three months. Wound eleven days old.

adhesive strips applied to protect the skin from tension. On the tenth day the wound was reopened for biopsy. It was found that the area was slightly swollen, but not inflamed and not fluctuant. A careful incision was made with every effort to put as little pulling strain on the wound as possible. As soon as the skin was divided it was found that the tissues under the skin had not healed at all and that the wound contained a firm dry blood clot. A section of skin including subcutaneous fat was removed for examination and showed no healing at all.

The blood clot was then scooped out, and pieces of the fascia which had pulled apart entirely were also removed. The latissimus fascia was then sutured and the skin sutured. That afternoon the subject was given 1 Gm. of ascorbic acid intravenously, and this was repeated daily for the next ten days while the subject remained on the same scorbutic diet. The wound healed promptly this time. At the end of the second ten days another incision was made directly across the area of the wound that had been pulled apart during the previous operation. This section, shown in figure 6, demonstrates normal healing.

The plasma level fell as rapidly as in the case of previous short period studies and after reaching zero at the end of forty-one days remained at this level. Determinations of the ascorbic acid in the white cell and platelet layer of centrifuged plasma were done for us by Butler and Cushman at the Children's Hospital

according to their new method.¹⁴ (They also checked our plasma determinations every two weeks.) The content of this layer, which is normally 30 to 40 mg. per hundred grams, fell much more gradually than the plasma level, reaching zero only after one hundred and twenty-two days. It was immediately after this date (the one hundred and thirty-second day) that the hyperkeratotic papules mentioned earlier in this paper first appeared, but only after twenty days more did the first characteristic petechiae appear.

Throughout the course of the experiment a gradual persistent loss of weight occurred. It is believed that this weight loss was due to inability to eat enough of the limited diet on account of its monotony (eggs, cheese, bread, butter, chocolate and coffee). There was no gain in the final ten day period on the diet while the subject was receiving ascorbic acid, but as soon as he went off the diet he gained a pound (0.5 Kg.) a day for a while.

The hemoglobin determinations were done for us by the Thorndike Memorial Laboratory by a modification of the Klett-Summerson photoelectric method. The original level was about 100 per cent of 15.6 Gm. per hundred cubic centimeters, and there was no appreciable fall for two months. Early in the third month a slight fall occurred which was rapidly reversed by adding 8 grains (0.52 Gm.) of ferrous sulfate daily to the diet. From the start a considerable burden was placed on

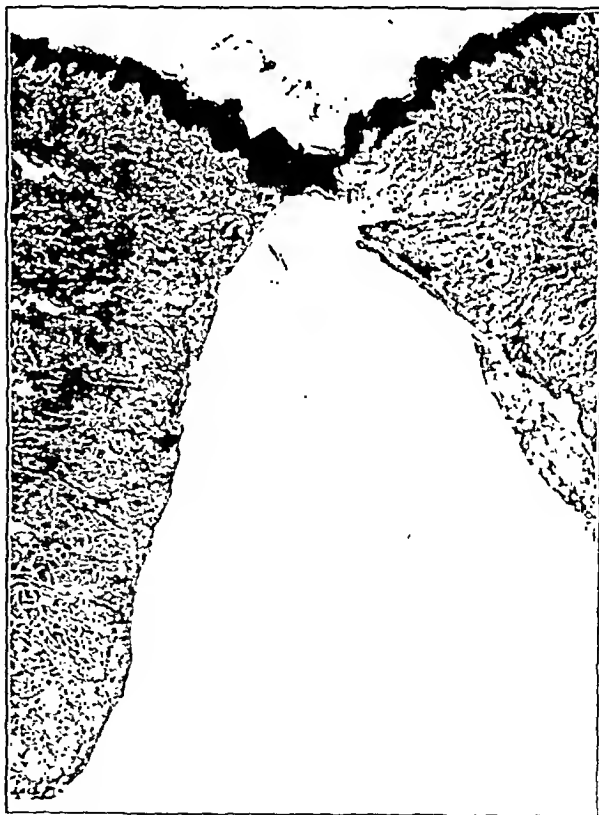

Fig. 4.—No healing at six months. Wound ten days old.

the hemopoietic system because of the steady daily loss of at least 10 cc. of blood for various determinations, and this was intensified by the four additional major

14. Butler, Allan M., and Cushman, Margaret: Distribution of Ascorbic Acid in the Blood and Its Significance, *J. Clin. Investigation* 19: 459-467 (May) 1940.

episodes of blood loss indicated in figure 2. At the time vitamin C was given to terminate the experiment the level was 93. During the next ten days a fall occurred to 76. But during the first five days of this period the blood loss was 150 cc. a day because of saturation experiments. The final loss was too rapid for the hemopoietic system to take care of.

From this part of the experiment it would appear that, in a six month period, vitamin C deficiency per se does not produce anemia.

As a result of this study to date it can be definitely stated that a blood plasma level of zero does not necessarily mean the presence of scurvy or even of a vitamin deficiency that is close to clinical scurvy, or that such a level indicates any necessary interference in wound healing. Confirmation of this statement is derived from

Fig. 5.—Formation of granulation tissue without intercellular substance.

Butler's work in that he showed that it is possible to cure clinical infantile scurvy by giving small doses of ascorbic acid to infants but without bringing their plasma vitamin C levels above 0.2 mg. per hundred cubic centimeters at any time.¹⁵ On the other hand, absence of wound healing was demonstrated in six months. At just what point between three and six months delayed healing begins we cannot say.

VITAMIN C INTAKE AND PLASMA LEVELS IN RELATION TO PULMONARY COMPLICATIONS OF SURGICAL CASES

Ralli and her co-workers¹⁵ have shown that the blood plasma level becomes adjusted rapidly to the average dietary intake of the vitamins in normal

persons when there is no excessive demand for the vitamin (such as occurs in fever or other causes of increased metabolism, or in patients with diarrhea or other causes of poor absorption). The level becomes adjusted in two weeks when the diet is altered and then kept constant.

In the present study an effort has been made to secure and record histories and, if possible, day to day calculations of the dietary intake with regard to vitamin C and to correlate the results with the data derived from plasma values. Such histories can be only roughly accurate and vary greatly in accuracy according to the intelligence of the patient and the patience of the interviewer.

However, in patients not suffering from fever or other abnormal metabolism of the vitamins there is a reasonable correlation between such dietary calculations and the values actually found.

It has been claimed that vitamin C is important in the defense against infections, but no conclusive proof of this claim has been made. Since pulmonary complications are common after surgical operations of magnitude it was decided to see whether such complications were more frequent in patients with high intake and levels of vitamin C than in those with low intake and levels. In making this study as many blood specimens were taken preoperatively as possible and a careful dietary history of the intake of food during at least one month up to the time of the operation. From the dietary histories calculations were made as to the approximate number of Sherman units of vitamin C in the diet. (Two Sherman units equals 1 mg. of vitamin C.) One hundred mg. daily of the vitamin is admitted by all workers to furnish an adequate supply to the normal person.

Before making up the table to be presented the cases were individually studied and classified in all possible ways. It was found that the intake of vitamin C and its level in the plasma of the patients were on the average both much lower than saturation levels. In fact only 17 out of 109 patients in the accompanying table had an intake of sufficient vitamin C to keep them saturated. For this reason it was decided to group the patients according to diet into three classes with the first, or highest, made up of those taking 50 units, or 25 mg. or more a day. Many of these patients had a slight vitamin deficiency, but all were probably well protected against scurvy. The intermediate class is made up of the patients taking from 20 to 49 units a day, and the lowest class, those taking less than 20 units. In the same way the patients were grouped according to the level of the reduced plasma vitamin C, with the high class those with levels from 0.50 mg. per hundred cubic centimeters and over. The intermediate class had levels from 0.20 mg. to 0.49 mg. and the low class up to 0.19 mg. per hundred cubic centimeters.

Many may think that the dividing lines given here are too low, but the real difficulty is that probably most of the patients in the lowest class are still not close to clinical scurvy. The plasma determinations on the patients were multiple in more than half the instances, and good checks of multiple determinations were made except in five instances. Two determinations were done on 31 patients, three on 11, four on 7, five on 5, and seven on 2 patients.

15. Ralli, Elaine P.; Friedman, Gerald J., and Sherry, Sol: The Vitamin C Requirement of Man Estimated After Prolonged Studies of the Plasma Concentration and Daily Excretion of Vitamin C in Three Adults on Controlled Diets, *J. Clin. Investigation* 18:705-714 (Nov.) 1939.

The operations consisted of various common procedure done for disease of the gallbladder. Eighty-six operations were simple cholecystectomy for acute (thirteen) and chronic (seventy-three) cholecystitis with and without stones. Eleven operations were cholecystectomy with exploration of the common duct. In 5 cases the common duct alone was drained. Cholecystostomy was done four times and cholecystostomy and choledochostomy three times.

The complications consisted of atelectasis nine times and bronchopneumonia eight times. It is often difficult to distinguish between these two diagnoses. In general the less severe cases were called atelectasis. If each diagnosis is studied separately the results are no different from the results given later in this paper. Also, if the cases of cholecystectomy for chronic cholecystitis are studied separately no difference is found. Statistical analysis of the accompanying table will show that there is no significant correlation of the diet or of the blood level to the development of postoperative pneumonia or atelectasis. It is curious that all three fatalities from pneumonia occurred in patients with both a high intake and a high level. The data on these 3 patients follow: In one the diet calculated was 180 units of vitamin C daily, and three plasma determinations were done showing 0.85, 1.08 and 0.98 mg. per hundred cubic centimeters. The next patient took 26 units daily, and her plasma level was 0.65 mg. The third took 55 units daily and showed 0.50, 0.53 and 0.48 mg. in the plasma. Two of these patients were obese.

Similar studies have been made in regard to other operations but will not be presented here. As far as we have gone they show the same lack of correlation mentioned previously. Other studies have been concerned with postoperative sepsis of wounds. Again no data need be presented as they show no correlation between sepsis of wounds and vitamin C.

Of considerable interest in this connection is the fact that the subject of the dietary experiment mentioned previously had only two minor "colds," lasting two days each, and no other infections during the experiment. This minimal amount of infection is unusual for this subject, who in past winters has invariably suffered from frequent and more severe infections of the upper part of the respiratory tract.

From this one cannot conclude that vitamin C is not necessary once infection has started and particularly in patients with serious long-continued sepsis when the reserves may be depleted more rapidly than is the case when lack of the vitamin in the diet is the only factor.

WOUND HEALING

The relation of wound healing to vitamin C in surgical patients is, of course, one of the most important studies that can be made. Our data on the following cases show certain aspects of this problem. It is recognized that wound healing is the result of many factors and that of primary importance is good surgical approximation with sutures that do not cut out and are not removed before the wound has reached enough tensile strength to hold together. Also the factor of decreased plasma protein is recognized but has not been studied in these cases.

REPORT OF CASES

CASE 1.—*History*.—L. L., a man aged 59, a fish handler, had carcinoma of the stomach. His diet had been inadequate for months. There had been preoperative loss of 50 pounds

(22.7 Kg.). Anterior gastroenterostomy was done, including closure with no. 2 catgut. No note was made as to whether fascia sutures were interrupted or continuous or as to the number of stay sutures.

Disruption occurred on the tenth day, within two hours of removal of the stay sutures, but there was no infection in the wound. The wound was resutured under local anesthesia.

Vitamin Study.—Two days after resuture, the blood plasma level of reduced ascorbic acid was 0.00. Ascorbic acid, 600 mg., was given daily intravenously for three days. After three days of such treatment the level was still 0.00. Then 300 mg. a day was given by mouth for seventeen days, at the end of which time the level was found to be 0.54 mg. per hundred cubic centimeters.

Since the vitamin level failed to rise from zero after 1.8 Gm. had been given in three days the deficiency

Fig. 6.—Normal healing at six months and ten days. Wound ten days old.

was severe and probably was the main cause of the disruption. However, the surgical technic was also open to question.

CASE 2.—*History*.—A. A., an unemployed man aged 65, had acute intestinal obstruction from a band. His diet had been excellent up to four days before operation, which was performed for separation of adhesions. The closure was not specified, except that it was in layers. Sutures were removed on the ninth day.

Separation of the wound occurred up to the peritoneum on the tenth postoperative day without infection in the wound, which was packed and strapped.

Vitamin Study.—The next day the blood plasma ascorbic acid level was zero.

In treatment 300 mg. daily of ascorbic acid was given by mouth from the tenth to the twenty-second postoperative day. The blood plasma level of ascorbic acid on the twelfth day was zero, on the nineteenth day 0.53 and on the twenty-third day 0.81.

In spite of the zero plasma level at the time of separation of skin and fascia it is believed that the fault in this case was surgical. It is not believed possible that a deficiency which could interfere with healing could occur in such a short time. In addition, seven daily doses of 300 mg. would not bring the plasma vitamin C content of a scorbutic patient up to the level of 0.53.

CASE 3.—History.—R. F., a man aged 38, a shipper, had an abscess of the appendix. His diet had been adequate up to his present illness, which had lasted ten days, with pain and vomiting, before admission and five days after admission. At operation drainage of the abscess without appendectomy was through a right rectus incision. Closure was done in layers with no. 2 chromic catgut. Disruption occurred thirty-three days post-operatively.

Vitamin Study.—A plasma vitamin C level of zero was found on the two days preceding the operation and on the fifteenth day after it. No vitamin was given the patient.

*Relation of Vitamin C Intake and Plasma Level of Reduced Ascorbic Acid to Pulmonary Complications in Patients Having Biliary Operations:
Diet = Sherman Units **

Plasma, Mg. per 100 Cc.	50 and Over	20-49	0-19	Total
0.50 and over.....	5*	0	0	5*
	20	10	0	30
0.20-0.49.....	2	3	0	5
	17	15	3	35
0.0-0.19.....	2	1	4	7
	7	11	17	35
Total.....	9*	4	4	17*
	63	36	20	109

* The figures are in the form of fractions. The numerator indicates the number of patients with pulmonary complications in each category and the denominator the number of patients among whom these complications arose. Two deaths occurred in the series not indicated on the chart. One occurred two months after operation for prostatic obstruction and the other from pulmonary embolism proved at autopsy. The asterisk indicates that 3 patients died of pneumonia.

The convalescence was stormy. Fever was present during the whole time from admission to disruption, and the intake of vitamin C was negligible. Vomiting occurred, and Wangenstein drainage was used a good part of the time for three weeks after the operation was performed.

Although presumably the patient had no important deficiency on admission (on the basis of dietary history) one cannot assume that the poor healing in this case was due to surgical factors or sepsis alone, as one has no information on the length of time it takes for scurvy to develop under these conditions.

CASE 4.—History.—M. A., an unemployed man aged 55, had an obstructing duodenal ulcer and tertiary syphilis. His diet had been inadequate and he had lost 50 pounds (22.7 Kg.). There had been use of large amounts of alcohol. There was complete retention of barium for six hours. As preoperative treatment, gastric drainage and hydration were done. A transverse incision was made and posterior gastroenterostomy was performed. The peritoneum was closed with continuous no. 0 chromic catgut and the fascia with interrupted no. 0 chromic catgut. Silk stays were tied over gauze. Sutures were removed on the sixth day and disruption occurred five hours later.

Vitamin Study.—One month after disruption the blood plasma level of vitamin C was zero on two different days. Ascorbic

acid tablets were not given but the diet had contained 175 units daily after the fifth postoperative day. Secondary sutures were removed on the twenty-second day after resuture.

In this case the disruption is believed to have been due in part to vitamin deficiency. We were informed that ascorbic acid had been given in adequate doses. After disruption it was found that this had been given by mouth, and probably none of it had been absorbed before the first operation.

In a case such as this, in which there is complete pyloric obstruction, the administration must be by the intravenous route. However, the removal of stay sutures on the sixth day is not good technic.

COMMENT

The observations made in the three sections of this report indicate that a careful study of the vitamin C status of surgical patients is valuable. Plasma determinations alone, if low, are not sufficient evidence on which to base treatment as the great bulk of patients with such levels are in no known danger from the deficiency. However, a history of months or years of inadequate intake, such as is seen so frequently in patients who have, or who think they have, gastric or duodenal ulcers, is ample evidence on which to base active treatment. Patients with diarrhea have not been presented in this paper, but such patients and patients with chronic sepsis probably need a higher intake of the vitamin to protect them from scurvy than those without these conditions. Therefore both fever and diarrhea must be considered in estimating the probable reserves of vitamin C in the patient's tissues. No evidence is presented here, but there is ample evidence elsewhere that most patients with scurvy are also suffering from multiple deficiencies. If treatment is indicated at all it is probably wise to give large doses of other vitamins when large doses of vitamin C are given. Of these it is our belief at present that thiamine hydrochloride and nicotinic acid are the most important ones for surgical patients. We now believe that such patients as 1 and 4 should be given ascorbic acid 1 Gm., thiamine hydrochloride 30 mg. and nicotinic acid 100 mg. daily for four days before operation.

CONCLUSIONS

1. A vitamin C free diet produced scurvy in one of us at the end of five months, and certain symptoms of it were severe at six months.
2. The ascorbic acid level of the blood plasma fell to zero in forty-two days and of the white blood cells in one hundred and twenty-two days.
3. A wound healed well after the subject had been three months on a scorbutic diet but not after six months.
4. There is no correlation between vitamin C intake and plasma levels and the incidence of postoperative atelectasis and pneumonia.
5. Vitamin C deficiency may be a factor in failure of some human wounds to heal.
6. A dietary history should be taken on all patients who come to major surgery and, if a long-continued marked deficiency of the intake of vitamin C is found, the patient should be given daily from 1 to 4 Gm. of ascorbic acid.

PLASMA VITAMIN C AND SERUM
PROTEIN LEVELS IN WOUND
DISRUPTION

JOHN B. HARTZELL, M.D.

JAMES M. WINFIELD, M.D.

AND

J. LOGAN IRVIN, Ph.D.

DETROIT

The problem of disruption and evisceration of abdominal wounds still remains unsolved, and the comparative importance of the various factors concerned with the production of this condition still remains in dispute. In a recent review of the literature, two of us¹ analyzed 1,458 collected cases, including 33 cases occurring in the surgical service of the City of Detroit Receiving Hospital. As a result of this study, we came to the following conclusions: The incidence of this catastrophe is probably about 1.5 per cent, with a mortality of about 35 per cent. The age, sex and race are unimportant factors. Seasonal variations may have some bearing as far as they predispose to respiratory infections. The period when disruption is most likely to occur is from the fifth to the tenth postoperative day, the eighth day being the average.

Logically the causes for failure of a wound to heal normally lie in the conditions affecting and retarding wound healing. Locally, one must consider incisions placed without regard to injury of the nerve and blood supply, as well as the severance of the transversus abdominis muscle, frequently making for a weak closure of the deep layer of the abdominal wall. Faulty technic resulting in traumatization of tissue and poor hemostasis, injudicious choice of and method of using suture material and the presence of infection are considered to predispose to wound disruption. In addition, those conditions tending to increase intra-abdominal tension, such as undue coughing, vomiting and intestinal distention, are thought to be of importance. They not only make for increased strain on the suture line but also interfere with immobilization of the part. In addition to the local factors pertaining to the wound itself, there are certain general factors which undoubtedly exert an influence on wound healing. The underlying disease or the presence of concurrent systemic disease resulting in a poor general condition of the patient must not be overlooked. Any condition of the patient resulting in a nutritional deficiency sufficient to produce low levels of ascorbic acid in the plasma and of protein in the serum of the blood must be considered important. There is also the possibility of an allergic response to catgut.

At the completion of this review, we felt more in doubt than ever regarding the relative importance of the various factors contributing to disruption of the abdominal wound. In reviewing the work of other writers and in summarizing our own case records, we were impressed that we were attempting to draw conclusions from inaccurate and incomplete data. Too frequently it has been necessary to study records which lack sufficient information to afford a basis for forming

satisfactory conclusions. The basic problem is one of wound healing, and it is difficult to evaluate its components even when a direct attempt is made in an individual case. If a study of a series of cases of wound disruption is to be of real value, it would seem logical to attempt analysis of each case as it occurs, with special emphasis on the contribution played by each of the many possible factors involved. Consequently we began to collect a new series of instances of disruption and to obtain data from a study of the patient rather than of the record.

It would seem logical to consider the distended, delirious patient, thrashing about in bed, coughing and vomiting, with a large infected abdominal incision, a candidate for wound disruption; yet his wound usually heals without separation. Consequently, when disruption of the wound does occur, the cause seems all too obvious. Pneumonia, diabetes and other serious concurrent systemic disease may predispose to disruption, but most patients suffering from these conditions have normal healing. On the other hand, consider the patient who has been afebrile for from three to five days, eating and drinking, urinating and defecating normally, without cough or nausea, whose incision appears to have healed and then, for no apparent reason, opens wide. This wound may appear clean, as though freshly incised, with no evidence that there has been any tendency to heal. In an attempt to find some cause, one is prone to ascribe this catastrophe to some definite inability on the part of the patient's tissues to heal. Possibly these factors are present also in the wound which disrupts in the presence of infection and with a stormy postoperative convalescence.

Recently there has been much interest about hypoproteinemia and vitamin C deficiency in relation to wound healing. The effect of low serum protein on wound healing has been studied by Carrel,² by Harvey³ and more recently by Thompson, Ravdin and Frank,⁴ who thus summarize the work on this phase of the subject:

Clark⁵ showed that on a diet high in protein there was no quiescent period in the repair of the wound in his dogs, the contraction beginning at once. In the review of Arcy⁶ on "Wound Disruption," one is struck with the fact that many of the factors associated with repair are directly or indirectly dependent on a diet high in protein. Thus, animals fed on a diet of this type showed accelerated fibroblastic proliferation. Cellular activity on the whole greatly increased. The quantity of secretion from the wound was decreased. A diet high in carbohydrate, to which alkalis had been added, increased the quantity of this secretion. The wounds of animals on an alkaline diet are said to be more easily infected.

Thus there are a number of factors, both in the dog and in the patient who is subjected to a prolonged and serious protein deficiency, which favors disruption of the wound. It has been observed that, when cultures of growing cells are surrounded by an overabundance of fluid of low viscosity, cell motility is retarded. Our experiments would tend to support the theory that certain of the amino acids are essential for the stimulating of tissue growth.

These authors found, in a high percentage of dogs with well advanced hypoproteinemia, that evisceration or breakdown of the wound will occur after laparotomy.

Thompson, Ravdin, Rhoads and Frank⁷ found further that catgut loses its tensile strength more rapidly in tissues in the presence of hypoproteinemia and also that they could restore serum protein to normal in hypoproteinemic dogs by means of intravenous injections of lyophile plasma, and in these animals the wound healed normally. Whipple and Elliott⁸ and Stone⁹ also believe that hypoproteinemia is a factor in the production of wound disruption.

Experimental data have shown that vitamin C deficiency plays an important role in wound healing in the laboratory animal. Aschoff and Koch¹⁰ in 1919 stated that in cases of scurvy the main primary deficiency was a lack of intracellular cement substance. Hojer¹¹ in 1924 verified these observations in the scorbutic guinea pig and noted changes which were due to a lack of collagen. Wolbach and Howes¹² demonstrated that the histologic basis for the failure of wounds to heal in the presence of vitamin C deficiency lies in the inability of the supporting tissues to produce and maintain intracellular substance, and later Menkin, Wolbach and Menkin¹³ found that microscopic sections of tissues of

cultures of fibroblasts a sudden increase in collagen fibrils when ascorbic acid was added to the medium. Wolbach¹⁷ states that deficiencies of vitamin C result in abnormalities of all intracellular substances having collagen as their basis and that its absence prevents the formation of the matrices of white fibrous tissue, bone, cartilage and dentin. He states further that in vitamin C deficiency the pathologic picture is produced by resorption of intracellular materials in both growth and reparative reactions. In such instances, if vitamin C is supplied either in natural foods or as the pure compound, histologic repair is immediately resumed.

There are many clinical observations which are in general agreement with the experimental data. Sokolov¹⁴ in 1932 recommended a diet rich in vitamin C and stated that it was his opinion that a partial vitamin C deficiency was a definite factor in poor wound healing. Archer and Graham¹⁹ believe that many patients with gastric disease are in a subscorbutic state owing to long periods of ill health and a restricted diet. They have observed that wounds of these patients heal badly. This is in general agreement with observations made by Hess.²⁰ Lazarus²¹ and McNealy and his associates.²² Youmans²³ believes that, although frank scurvy is rare, in contrast, mild or latent scurvy or a slight deficiency in vitamin C is probably very common. Ingalls and Warren²⁴ report 20 cases of peptic ulcer in all of which there were low vitamin C values. They believe that there is an important relationship between low vitamin C values and the inability of an ulcer to heal and its tendency to bleed. Therefore they urge a check of the vitamin C before surgery is resorted to in such cases. Lanman²⁵ says that asymptomatic scurvy is far more common in infants and children than is realized and presents evidence to show that a partial vitamin C deficiency is of importance in the failure of surgical wounds to heal in human beings.

Madison and Manwaring²⁶ have shown that there is experimental evidence which would indicate that vitamin C aids the body in defense against infectious diseases and that large doses increase antibody production. This is borne out by the work of Smith and McConkey.²⁷ Lund,²⁸ Wolfer and Hoebel²⁹ and Bartlett, Jones and Ryan³⁰ have recently shown that there is a decrease in the concentration of the plasma ascorbic acid following surgical operations. We also have found this to be true. With regard to the 14 cases reported by Bartlett, Jones and Ryan,³⁰ all but 1 presented gastric

TABLE 1.—General Condition in Twenty Cases of Wound Disruption

General Condition	Underlying Disease
Good 9 cases	2 gunshot wounds of the abdomen 1 ruptured peptic ulcer 1 duodenal ulcer with obstruction 1 acute appendicitis 1 chronic infection of gallbladder with stones 1 fibroid uterus 1 ventral hernia 1 chronic appendicitis
Fair 8 cases	1 volvulus of sigmoid flexure 1 perforated carcinoma of stomach (resected) 1 carcinoma of stomach 1 intestinal obstruction 1 chronic appendicitis 1 acute appendicitis 1 chronic infection of 1 simple exploration
Poor 3 cases	1 acute appendicitis with perforation and liver abscess 1 carcinoma of the pancreas with jaundice 1 carcinoma of the stomach (inoperable)

scorbutic animals demonstrated the deposition of increasing amounts of intracellular cement substance depending on the amount of vitamin C administered. Taffel and Harvey¹⁴ report that the tensile strength in stomach wounds of the partially scorbutic guinea pig is much decreased from the eighth to the tenth day. Lanman and Ingalls¹⁵ have shown that guinea pigs maintained on approximately one fifth of the minimal preventive dose of ascorbic acid exhibited healing of operative wounds inferior to those of normal controls. Jeney and Törö¹⁶ were able to demonstrate in "in vitro"

or duodenal ulcer or a malignant growth of the gastrointestinal tract, while 1 was a very toxic case of exophthalmic goiter. We have found that these types of cases show low values as a routine. We have found also that an excess of 1,000 mg. of vitamin C intravenously is required for saturation in these cases for a twenty-four hour period. Consequently, in view of the fact that all presented low levels of vitamin C in the plasma on initial examination, and in all but one a single dose of 1,000 mg. was given from one day to fourteen days preoperatively, it is our belief that all these cases undoubtedly, if tests had been made one hour before these operations, would have shown very low values. In those cases in which vitamin C determinations were made on the day of operation, the values were low. We have found that the average postoperative drop in eleven controls with normal preoperative values was about 0.05 mg. per hundred cubic centimeters of blood plasma. Lund²⁸ states that in cases in which the preoperative value is low, the postoperative decrease is proportionately greater. He believes that this postoperative drop may be explained by the decreased intake and also by an increased metabolism resulting from the usual postoperative fever. He also believes that the demand of the newly formed tissues which are produced in the

ascorbic acid and serum protein. All the analyses were performed as quickly as possible, the time elapsed not exceeding two hours in any instance. The plasma concentration was determined by the method of Mindlin and Butler³³ and the serum protein concentration by

calculation from the total nitrogen obtained by micro Kjeldahl analyses.³⁴

Table 1 groups the 20 cases of wound disruption into three classes, indicating whether the condition was considered good, fair or poor at the time of the primary operation.

Surprisingly enough, the condition in all but three of these cases was thought to be good or fair at the time the case was seen by the surgeon. Malignancy has been emphasized by many as a condition predisposing to disruption. In our review of 1,458 cases 320, or 22 per

healing process may use the vitamins at a rate faster than that for normal tissue growth. Wolfer and Hoebel²⁹ stress the large dosage required to bring a patient in a depleted state to, and maintain him at, a state of saturation. Vorhaus³¹ stresses the importance of excessive vitamin therapy, both before and after operation.

The concept of vitamin C deficiency with regard to difficulties in wound healing is not new, descriptions of scurvy having appeared in the literature since the time of Hippocrates. Richard Walter's³² account of Lord Anson's "Voyage Around the World" in 1740 vividly describes the effects of scurvy among the crew: "Scars of wounds that had been for many years healed, were forced open . . . one of the invalids . . . who had been wounded fifty years before . . . and had continued well for a great number of years past, yet, on his being attacked by the scurvy, his wounds in the progress of the disease broke out afresh and appeared as though they had never been healed."

During the year 1939, with the help of colleagues from the staffs of Harper and Grace hospitals, we collected twenty cases of disruption of the abdominal wound at the time it occurred. In each instance the patient was either seen by us or the case was discussed at length with the attending surgeon or the surgical resident in charge, and in each instance samples of blood were obtained for the determination of plasma

presenting malignant growths of the gastrointestinal tract, as well as those presenting gastric or duodenal ulcers, show almost universally low values.

Table 2 shows that, as far as this series is concerned, disruption occurs more frequently following vertical incisions.

TABLE 5.—Five Clean Cases in Which Postoperative Complications Occurred

Disease	General Condition	Post-operative Course	Plasma Ascorbic Acid, Mg. per 100 Cc.	Serum Protein, Gm. per 100 Cc.	Albumin-Globulin Ratio	Results
Duodenal ulcer with obstruction	Good	Distention, vomiting, 3 transfusions	0.42	6.30	1.4	Evisceration, died
Suspected carcinoma of stomach unconfirmed	Fair	Persistent cough	0.35	5.60	1.4	Evisceration, died
Cholecystitis and cholelithiasis	Good	Vomiting, cough, ileus	0.30	5.80	...	Evisceration
Acute appendicitis	Good	Distention, cough	0.30	5.55	1.2	Evisceration
Gunshot wound of abdomen	Good	Distention, atelectasis, pneumonia, sulfanilamide, sulfapyridine	0.31	5.90	1.3	Evisceration

It may be argued that this is to be expected, as the vertical incision is the more commonly used. However, it will be seen that the only cases in which evisceration occurred following disruption were those in which the vertical incision was used. As might be expected in the presence of infection and the formation of adhesions, evisceration is less frequent. As a matter of fact, the only case of a clean vertical incision in which evisceration did not occur was one in which the peritoneum was not opened. No evisceration has yet occurred through the disrupted wound in a transverse incision. We have used this incision many times in the past three years, and especially is it to be recommended in the upper part of the abdomen, for here most vertical incisions not only impair the nerve and blood supply but also sever the tendinous fibers of the transversus abdominis muscle, which fuses with the peritoneum in the midline.³⁵ This makes for a weak closure of the deep layer. If these fibers are split transversely they are easily approximated in a firm closure.

Table 3 illustrates that, as far as this small series is concerned, the type of suture material seems to make but little difference with reference to wound disruption.

That no type of suture material is proof against disruption is in agreement with observations made in our review; this was also emphasized by Madelung³⁶ in his classic work in 1905. We came to the conclusion that tension sutures were of questionable value but that they might tend to prevent evisceration should disruption occur. These data likewise indicate that tension sutures are not positive protection against wound disruption or evisceration, since tension sutures were employed in seven of the thirteen cases in which evisceration occurred.

Tables 4, 5 and 6 deal with the plasma vitamin C and serum protein levels in the 20 cases of wound disruption. It will be noted that the serum protein was

below normal in every instance in which wound disruption occurred and that, with a single exception, this was likewise true of the plasma ascorbic acid.

Table 4 comprises a group of 9 cases in which the wound appeared perfectly clean and in which the convalescence prior to disruption had been absolutely uneventful. In each instance the disruption occurred without warning; the patient had had a normal postoperative course and had been afebrile for three or more days, and there had been no vomiting or distention. In all except 1, the disruption was without apparent physical cause, and the plasma vitamin C and serum protein values of the blood plasma were low. This case, which was one of carcinoma of the pancreas with obstructive jaundice, deserves special comment:

A man aged 73 appeared to be in very poor condition. Preoperatively the plasma vitamin C value of the blood was 0.37 mg. and the serum protein value 5.36 Gm. per hundred cubic centimeters. In the course of a series of saturation studies we have found that from 1,000 to 2,000 mg. of ascorbic acid over a period of from three to four days was sufficient to elevate the blood ascorbic acid to normal levels. Consequently, we gave the patient vitamin C in amounts which were found to produce saturation in the average of the cases studied. A transfusion was also given. In addition, dried bile and vitamin K were administered until the prothrombin time was within normal limits. A subcostal incision was made and an enormously distended gallbladder was found and a cholecystoduodenostomy was performed. The convalescence was surprisingly smooth and uneventful. On the fifth day the wound separated down to the deep layer. The transversus abdominis fascia and peritoneum were well healed and did not separate. The patient was taken to the operating room, where a careful inspection of the wound revealed a large, partially organized hematoma, approximately 5 by 5 by 3 cm., which had actually forced the anterior fascia and skin apart. The wound was clean and there was good evidence of healing. A secondary closure was

Ruptured peptic ulcer	Good	Mild wound infection	0.35	5.55	1.2	Evisceration

* Wound disrupted following a previous operation many years before.

performed, followed by an uneventful recovery. It will be noted that, although the serum protein was low, the vitamin C concentration was practically normal. We consider that separation of this wound was due primarily to the formation and pressure of the hematoma. It is quite likely that in this case the wound would have separated even though the serum protein had been normal.

Table 5 groups five clean cases in which postoperative complications, in addition to the complication found in the wound, occurred. In each of these cases there was the complicating factor of an increase

in intra-abdominal tension. One patient received three transfusions, and it will be noted that this patient had the highest serum protein value in the series. The last patient in this series, a 12 year old boy with two gunshot perforations of the stomach, developed type XVIII pneumonia. He was treated with sulfanilamide and sulfapyridine. According to the investigations of Bricker and Graham,³⁷ wound healing

TABLE 7.—Summary of Analyses in Twenty Cases of Wound Disruption: Average Values for Plasma Ascorbic Acid and Serum Protein Concentrations

Group	Plasma Ascorbic		Serum Protein		Albumin-Globulin Ratio
	Number of Patients	Acid, Mg. per 100 Cc.	Range, Mg. per 100 Cc.	Protein, Gm. per 100 Cc.	Range, Gm. per 100 Cc.
Normal values reported in the literature	0.7 to 2.0	7.11	6.5 to 7.7
Normal values in our series (students)	20	0.96	0.64 to 1.86	7.19	6.51 to 7.46
Our group of hospitalized patients with benign conditions	30	0.87	0.49 to 1.61	6.93	5.90 to 7.75
Wound disruption (infected wounds)	6	0.33	0.28 to 0.59	5.84	5.40 to 6.20
Wound disruption (clean wounds)	14	0.36	0.13 to 0.66	5.83	5.44 to 6.30
		Standard Deviation	Test of Significance	Standard Deviation	Test of Significance
Infected wounds		0.0538	10.1	0.166	8.2
Clean wounds		0.062	9.9	0.174	7.6

is adversely affected by the administration of sulfanilamide. In this case the use of both sulfanilamide and sulfapyridine quite probably was a factor in creating the wound disruption. In each of these cases the wound appeared clean, with no evidence of healing, and in each the serum protein and vitamin C concentrations of the blood plasma were low.

Table 6 comprises 6 cases in which there was a definite wound infection. In all except the last case, there were moderate to severe stormy postoperative courses. In the last case, in which there was ruptured peptic ulcer, operation was done through a high right rectus incision. We would note here in passing that at the City of Detroit Receiving Hospital 234 operations on ruptured peptic ulcers were done through this type of vertical incision with an incidence of wound disruption and evisceration of 2.6 per cent,³⁸ this with a recorded hospital incidence of 0.5 per cent, which is very high (we feel that both these figures are too low, as during this period many partial disruptions without evisceration undoubtedly went unrecognized). During 1938 we operated on 39 of these patients through a short transverse incision similar to that described by Amendola³⁹ without a single evisceration. We not infrequently see these wounds become severely infected and break down, but owing to the location and type of this incision we do not expect serious wound separation in these cases. In checking 40 gastric and duodenal ulcer cases, in half of which on entrance to the hospital perforation existed, we found that almost universally low serum protein

and plasma vitamin C values were present. The incidence of wound disruption might be expected to be high because of nutritional deficiencies.

Table 7 summarizes the 20 cases of wound disruption in this series. The normal values as collected from the literature,⁴⁰ as well as our own series, for plasma ascorbic acid are from 0.7 to 2.0 mg. of ascorbic acid per hundred cubic centimeters of blood plasma. The normal total serum protein values reported in the literature vary from 6.5 to 7.7 Gm. per hundred cubic centimeters, 7.1 being the average. Our data from normal subjects were obtained from college students and laboratory workers. It will be seen that these averages are well within the limits reported in the literature as normal. Our data, obtained from a group of 30 hospitalized patients with benign lesions (hernias, appendicitis, cholecystitis, fractures and the like), were also within normal limits but tended to be slightly lower. It will be seen that the average values of the plasma ascorbic acid and serum protein concentrations in the wound disruption cases are decidedly lower than normal.

COMMENT

There are undoubtedly many patients operated on when in a subcurvy state who have normal wound healing, but the relationship of low vitamin C and low serum protein to poor wound healing of those who have difficulty in wound healing cannot be overlooked.

In a series of 1,458 collected cases of wound disruption 320, or 22 per cent, presented carcinomas, while 195, or 13.4 per cent, presented gastric or duodenal ulcers. In such cases the nutritional condition of the patient, as reflected by serum protein and vitamin levels, is very likely to be poor because of restricted diets and, in the case of serum protein concentrations, because of decreased production of the proteolytic enzymes.

During the past year, in the course of some 200 determinations, we found that persons suffering from carcinoma of the gastrointestinal tract or gastric or duodenal ulcers almost universally show low vitamin C and serum protein values. It has been noted recently that some patients will show a drop in their vitamin C levels following certain operative procedures. We have found this to be true. We know also that in the presence of infection the body requires a greater intake of vitamin C in order to maintain a normal degree of saturation.

CONCLUSION

We would emphasize Mason's⁴¹ statement that "the urge to heal is almost as great as the urge to live." Wound healing is affected by many factors, and the nutritional condition of a patient is a most important one. Either to maintain life or to repair tissue there must be a supply of proteins, fats, carbohydrates, minerals, water and vitamins. Periods of inanition or faulty nutrition are likely to deplete the carbohydrates and fat stores and to lower serum protein and vitamin levels. We almost universally supply carbohydrate and salts by routine intravenous administrations, but, generally speaking, if a transfusion is given it is because the hemoglobin and the red blood cell count are low

rather than because of a low serum protein, and the vitamins are forgotten entirely. It would seem logical that, if normal healing is to be expected, the ascorbic acid and serum protein levels of the blood plasma ought to be brought to and kept at normal concentration.

7815 East Jefferson Avenue.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. LUND AND CRANDON AND
DRS. HARTZELL, WINFIELD AND IRVIN

DR. THOMAS T. MACKIE, New York: These two papers are important contributions not so much because of correlation between deficiency of a particular vitamin or low plasma protein levels and certain surgical complications as because of the broader implications of nutrition in wound healing and surgical convalescence. I likewise have found that a drop of the plasma vitamin C is common in the postoperative period. There is ample experimental evidence to support the role scurvy plays in failure of wound healing. Wolbach has shown that in this condition there is defective formation of collagen. In scorbutic guinea pigs there is obvious reduction of the tensile strength of wounds when contrasted with the normal animal, beginning about the fifth postoperative day. Although single determinations do not permit the conclusion that the patient is on the verge of scurvy or that failure of healing will occur, they indicate that a greater hazard may well exist. These papers permit two conclusions. Demonstration of low plasma ascorbic acid values or low plasma protein levels indicates an abnormal state of nutrition. Evidence of one or more such deficiency must be accepted as indicating the probable presence of others. Both experimental and clinical studies indicate that these multiple deficiencies may contribute to several important postoperative complications, including wound disruption, hemorrhage, gastric atony, persistent vomiting, distention and paralytic ileus. Such observations have led me to believe that the preoperative management of elective surgical cases should include utilization of those clinical and laboratory methods which are available at present to evaluate the nutritional states of the patient. Evidence of one deficiency must be accepted as indicative of others, and appropriate measures should be undertaken. In any consideration of the role of the vitamins it is important to remember that their primary function lies in their role as the chemically active portion of many coenzymes which are essential for the normal metabolism, and consequently the normal function, of all living cells.

DR. JONATHAN RHOADS, Philadelphia: Drs. Hartzell, Winfield and Irvin have done remarkable work in collecting twenty cases of this relatively infrequent complication and in obtaining specimens from the patients at the time of the accident. The experiments on wound healing carried out in dogs by Dr. Ravdin and his associates showed that severe depletion of the plasma proteins rendered these animals incapable of normal fibroplasia. Wound disruption was frequent in their dogs, and sections of the wound as late as fourteen days after operation showed but few fibroblasts. Dogs similarly prepared prior to operation but which received lyophilic plasma immediately after operation healed in a normal manner. Vitamin C deficiency interferes with wound healing by a different mechanism, but its relation to wound healing is equally susceptible of proof in the experimental animal. However, while these investigations strongly indicate that these two deficiency states may prevent normal wound healing, to show that they really are of practical importance in patients required just such a study as Dr. Hartzell and his associates have presented. As they have rightly pointed out, there are undoubtedly many possible causes of wound dehiscence and it is indeed surprising that all these twenty patients should show hypoproteinemia and that nineteen of them should show a C avitaminosis. It is important to realize that hypoproteinemia connotes not only a reduced concentration of protein in the circulating plasma but also a depletion of the labile protein stores of the body and a reduction in the total plasma volume. Thus, in some of the hypoproteinemic dogs in Whipple's laboratory it was found that the plasma volume was

reduced about 50 per cent. This probably results in some alterations of the peripheral circulation. Whether the delay in fibroplasia which Ravdin and his collaborators have observed in the hypoproteinemic dog is due to the alteration in the colloid osmotic pressure of the blood, to the effect on the circulation of the associated decrease in blood volume or to the lack of labile protein for repair purposes is not known but is the subject of continued investigation.

DR. MARSHALL K. BARTLETT, Boston: It is clear after listening to the paper of Drs. Hartzell, Winfield and Irvin that wound healing as seen in the clinical patient is a complicated problem with many factors, and it probably will take a long time to sort these out and assign the proper importance to each. Considering vitamin C as one of these factors, I think that Drs. Lund and Crandon are to be congratulated on the prolonged experiment they carried out in producing clinical scurvy. The striking thing about it is the length of time it took to produce clinical scurvy in this young man. One factor in that, of course, may be that he was in most excellent health and probably saturated with vitamin C and all the other necessary factors at the start. In relation to that, I hope you all noticed how long that man's plasma vitamin C level was zero before any evidence of interference with wound healing could be shown. It may well be that the determination of vitamin C level in the white cells may prove to be of far more importance in predicting the presence of impending scurvy than a simple determination of the plasma vitamin C.

DR. CHARLES C. LUND, Boston: We have shown that vitamin C deficiency can produce absolute failure of healing, but I think this is rather uncommon in clinical cases. The evidence we have already points in this direction. The splendid work of Whipple and his associates must never be forgotten. A few years ago, just before vitamins were considered and before plasma protein was considered, they reduced the wound disruptions at their hospital 80 per cent merely by improving their surgical technic. We must never forget that we are surgeons by trying to get away with poor technic by feeding vitamins. It can't be done. The same thing applies to the plasma protein. I haven't studied it, but I think it is perfectly possible that reduced plasma protein is more important in relation to the chemistry of healing than is vitamin C. In going over the cases that I have not had time to talk about in detail today, most of them are failures of surgical technic rather than the result of any chemical deficiencies, and, of the ones that are chemical, even they have in some cases some questionable factor of technic. Dr. Mackie mentioned that the vitamins are of fundamental importance in the nutrition. Crandon got very weak at the end of this experiment. He took a test on a treadmill at the Harvard Business School fatigue laboratory, and on the treadmill he lasted just sixteen seconds. Dr. Dill tells me that the weakest Harvard student he ever tested went a minute. At the termination of this experiment he stayed on his diet for ten days while he was given vitamin C alone. On the tenth day his muscular strength had come back to the point that put him in the class with the weakest Harvard student, and without any gain of weight and without any change in diet, so that there couldn't have been any other factor than vitamin C. Subsequent to this when he went off the diet he gained a pound a day for the next two weeks and we have still further work to do along the line of further tests as he develops his muscular strength back. Therefore this vitamin must have some function of importance that goes beyond wound healing. However, we do not know that it has anything to do with surgery now unless muscular weakness is a factor in surgical results, as it well may be.

DR. JOHN B. HARTZELL, Detroit: Dr. Singleton is an advocate of the transverse type of incision. Because of the limits of time we omitted the data which relate to the type of incision with reference to the incidence of evisceration. While it may be argued that it is to be expected that the vertical incision eviscerates more commonly because it is more commonly used, our data indicate that evisceration does not occur in the type of incision advocated by Dr. Singleton. Likewise, we omitted in our discussion the relationship of infection, but this will be found in the published paper, as well as the fact that no type of suture material is proof against disruption.

THE SYNTHETIC ESTROGEN
STILBESTROL

AN EXPERIMENTAL AND CLINICAL EVALUATION

CHARLES MAZER, M.D.
S. LEON ISRAEL, M.D.
AND
ELKIN RAVETZ, M.D.
PHILADELPHIA

The natural estrogens have proved their value in the treatment of the severe menopausal syndrome, vaginitis of children and senile women, and certain types of amenorrhea, migraine and abnormal breast hyperplasia. Two principal drawbacks attend the clinical use of the natural estrogens—the high cost, especially when large doses are required, and the loss of potency when administered orally. The advantage of the oral administration of endocrine products in the attempt to overcome a relative or actual deficiency is apparent when one recalls that the various hormones are normally produced in minute quantities at a relatively steady rate. This process cannot be imitated by hypodermic injections at intervals of two or three days.

For these and other less important reasons, the need of an orally potent, synthetic estrogen is constantly engaging the attention of the biochemist and the clinician. When Dodds and his associates¹ announced in 1938 the synthesis of the highly active estrogen stilbestrol, the product was welcomed for clinical trial with guarded hopefulness throughout the world.

Stilbestrol is a stilbene derivative, unrelated to the sterols and totally foreign to the human economy. The acetate and propionate of stilbestrol have equal estrogenic properties and possess the additional advantage of slower absorption when given parenterally.² In the investigation of stilbestrol herein reported, we set out to determine:

1. The comparative potency of the product in the animal in terms of the international unit of estrone.
2. Its rate of absorption and excretion in the human being.
3. Its therapeutic effectiveness as gaged by its ability to produce growth of the endometrium and withdrawal bleeding in castrated, menopausal and amenorrheic women; and by its relative effectiveness in relieving the various conditions wherein the natural estrogens are successfully employed.
4. The incidence of toxic symptoms in the human being.
5. The possibility of tissue damage in the human being.
6. Its damaging effects on the vital organs of animals.

THE BIOLOGIC POTENCY OF STILBESTROL IN
TERMS OF THE INTERNATIONAL
UNIT OF ESTRONE

An international unit of estrone is 0.1 microgram of the substance. Ten international units (1 microgram) of estrone equals 1 Allen-Doisy rat unit. The relative potency of other estrogens may be ascertained in terms of the international unit by assay against a known number of units of estrone.

Repeated assays in our laboratory uniformly showed that 0.2 microgram of stilbestrol, given hypodermically in three divided doses, evokes vaginal estrus in the

adult castrated rat—the Allen-Doisy rat unit. Its biologic potency when given hypodermically is therefore five times greater than that of estrone and equal to that of estradiol benzoate. Of greater interest is the fact that the introduction of 1 microgram (5 rat units) of stilbestrol into the stomach of the castrated rat produces full estrus. It requires either 20 micrograms (20 rat units) of estrone or 2 micrograms (20 rat units) of estradiol, given in like manner, to produce the same effect.

It will be seen later that the ratio between the oral and the hypodermic doses of stilbestrol is 5 to 1 in the human being as well as in the rat, in contrast to a ratio of 20 to 1 in terms of the rat unit for the natural estrogens.³

THE RATE OF ABSORPTION AND EXCRETION
OF STILBESTROL

The optimal dosage of a given estrogenic substance must ultimately be determined by trial and error. Except in instances of vaginitis in children and senile women, dependence on the character of the vaginal smear is clinically unsound. Shorr, Robinson and Papanicolaou,⁴ who have studied the subject extensively, state that "there is no necessary correlation between the degree of symptomatic improvement and the

extent of the smear change. The level of the smear change at which amelioration of symptoms takes place varies with the individual patient."

Studies on the rate of absorption and excretion of estrogens likewise give little information concerning optimal dosage. Such data do, however, determine the maximum intervals at which hypodermic treatment must be given. If, for instance, the quantity injected were totally eliminated in twenty-four hours, injections at intervals of three or four days would leave the patient without the benefit of the estrogen during most days of treatment. As seen in table 1, quantities of estrogenic substance far greater than those current during the premenstruum of normal women are present in the urine of castrated women on the third day after a single injection of 1 or 2 mg. of stilbestrol. Since the amount excreted in the urine reflects fairly accurately the relative content of estrogen in the blood, it is fair to assume that injections of adequate quantities twice weekly are sufficient for clinical purposes.⁵

That stilbestrol is readily absorbed from the gastrointestinal tract is evident from the fact that as little as

0.2 mg. given daily to the castrated woman maintains a level of estrogen excretion comparable to that current in the normal woman during the week prior to menstruation (table 2).

THE THERAPEUTIC EFFECTIVENESS OF STILBESTROL
It is obviously impossible to review, in this short presentation, the extensive clinical reports on the use of stilbestrol in the various conditions in which the natural estrogens are commonly employed. We are

limited by necessity to an evaluation of the results obtained in the 189 cases embraced in this report (table 3). These results, summarized in the following paragraphs, confirm, in the main, the observations of others that stilbestrol produces all the clinical effects of the natural estrogens in those who tolerate the substance.

EFFECT ON THE MENOPAUSAL SYNDROME

One hundred and fifty patients presenting severe menopausal symptoms, such as frequent flushes, headache, depression, insomnia and impairment of memory, were given from 0.2 to 5 mg. of stilbestrol daily by the oral route or every fourth day parenterally. Thus the total oral dose was four times the hypodermic dose, since it was taken daily and not every fourth day.

Twenty-eight of the group (18.7 per cent) showed symptoms of intolerance to the substance at an early stage of the treatment, irrespective of the mode of administration. The remaining 122 patients received treatment for periods of from eight to forty weeks. The wide variation in length of treatment is partly accounted for by the appearance of intolerable side-effects in eight patients after two or more months of treatment.

Eighty-three of the 122 patients (68 per cent) were totally relieved and 34 (27.9 per cent) were only partly relieved of their symptoms during the period of observation of several months. The symptoms of the remaining

5 patients (4.1 per cent) were not influenced by the treatment (table 4). The results in the 122 patients who tolerated the substance for at least two months were essentially in accord with the majority of published observations on the use of stilbestrol for the relief of the menopausal syndrome and are, moreover, significant because they were achieved by means of oral administration alone in 58 (49 per cent) of the patients treated.

The effectiveness of stilbestrol given orally is in striking contrast to the inactivity of the natural estrogens, which lose 95 per cent of their potency when thus administered.⁶ The clinical use of stilbestrol would, indeed, be highly advantageous were it not accompanied by side-effects in a considerable number of instances.

Sporadic uterine bleeding either during or after treatment occurred in 15 of the 79 postmenopausal women (19 per cent) in the group of 150 climacteric patients—an incidence of estrogen-induced bleeding comparable to that observed in postmenopausal patients treated with equivalent hypodermic doses of the natural estrogens. The severity of the uterine bleeding in some of the treated patients necessitated temporary withdrawal of treatment, uterine curettage or the simultaneous administration of testosterone propionate. In the 6 who were curetted while bleeding, a hyperplastic endometrium was obtained. The induction of uterine bleed-

ing from an overgrown endometrium by the oral administration of the substance to women who had not menstruated for years is further evidence of its high degree of potency when given by this route. The oral administration of the commercially available natural estrogens rarely evokes uterine bleeding in either menopausal or amenorrheic women.

EFFECT ON AMENORRHEA

In amenorrheic women, the natural estrogens have been employed in the hope of increasing the size and vascularity of the uterus, thereby rendering it more responsive to an improved pituitary-ovarian activity brought about by other agents. To these patients, the estrogen must be administered intermittently (only two weeks of the month) in order to avoid inhibition of the anterior hypophysis, which would defeat the very purpose of the treatment. In order to induce bleeding from a well developed endometrium, a total of 50,000 rat units of estrogen (the equivalent of a half million international units of estrone) must be given hypodermically in five divided doses.⁷ Uterine bleeding, grossly indistinguishable from normal menstruation from a highly proliferative endometrium, almost invari-

ably follows within a week or ten days the withdrawal of such intermittent treatment.

Stilbestrol was thus employed for 19 amenorrheic women. The treatment of 4 was stopped after the first or second day because of nausea, vomiting or epigastric pain. The hypodermic administration of at least 10 mg. of stilbestrol (equivalent to 50,000 rat units or a half million international units of estrone), given in five divided doses over a period of two weeks, produced menstruation-like bleeding in six of seven attempts. Smaller doses similarly administered failed to evoke more than mere staining. The oral administration of 5 mg. daily over a period of ten days (a total dose of 50 mg.) was successful in all of seventeen attempts. Smaller total doses, such as 20 to 30 mg., similarly administered failed to induce withdrawal bleeding in seven of nine attempts (table 5).

It is interesting to note that the ratio between the oral and the hypodermic doses of stilbestrol in the induction of withdrawal bleeding in amenorrheic women is five to one as it is in the induction of artificial estrus in the castrated rat. Moreover, the minimum effective, total hypodermic dose of stilbestrol in terms of the international unit of estrone is identical as far as withdrawal bleeding is concerned with that of the natural estrogens.

TABLE 5.—*Stilbestrol-Induced Withdrawal Bleeding in Fifteen Amenorrheic Women*

	3 mg.	30 mg.	8	2	6
	2 mg.	20 mg.	1	0	1

* Several attempts were made in some of the 15 patients.

EFFECT ON LACTATION

Eight puerperal women who for various reasons could not nurse their infants were given daily from 3 to 10 mg. of stilbestrol orally for a period of from two to four days with complete suppression of lactation—an effect comparable to that obtained with large doses of the natural estrogens given hypodermically.⁸ None of these 8 patients exhibited any side effects, such as nausea, vomiting or abdominal pain, despite the large doses administered. The unusual tolerance of pregnant and puerperal women to large doses of stilbestrol was noted by Priscilla White,⁹ Greenhill¹⁰ and others.

EFFECT ON MIGRAINE

Four patients with frequent and severe attacks of migraine received stilbestrol. Two of them, given the substance orally in daily doses of 1 and 2 mg. for three and two months respectively, tolerated it well and were relieved of the migraine during the period of treatment. The remaining 2 patients received 2 mg. of the substance hypodermically every third day for a period of one month without untoward reactions, but the migraine was not influenced by the treatment.

Similar results in migraine are obtainable with comparable doses (5,000 to 10,000 rat units) of the natural estrogens given hypodermically at intervals of four days.⁵

EFFECT ON JUVENILE VULVOVAGINITIS

Four children with vulvovaginitis were treated with stilbestrol. Two of the 4 received 1 mg. daily by mouth for a period of one month without side-effects. The vaginal epithelium became intensely cornified within

two weeks, and the vaginal smears thereafter remained free from pus and pathogenic bacteria during follow-up periods of three and eight months respectively. The hypodermic administration of 1 mg. of the substance every third day for a period of six weeks produced a similar result in the other 2 children. Owing to the paucity of clinical material, the minimum effective dose of stilbestrol in this condition was not ascertained.

THE INFLUENCE OF STILBESTROL ON THE INSULIN REQUIREMENT OF DIABETIC PATIENTS

The ability of large doses of the natural estrogens to lower the blood sugar level of diabetic patients was reported by us¹¹ in 1935 and, more recently, by Spiegelman.¹² These clinical observations are in accord with the experimental findings of Barnes and his associates¹³ that the blood sugar level of pancreatectomized dogs injected daily with 200 rat units of estrogen is appreciably decreased.

TABLE 7.—*The Time of Appearance of Toxic Symptoms in Relation to the Mode of Administration of Stilbestrol*

Time of Appearance of Toxic Symptoms	Route of Administration		Patients with Toxic Symptoms	
	Oral	Hypodermic	No. of Patients	Percentage
Early.....	27	5	32	76.2
Delayed.....	2	8	10	23.8

Theoretically, the fall in the blood sugar in the diabetic, both human and animal, following injections of the natural estrogens is attributable to inhibition of the diabetogenic function of the anterior lobe of the pituitary, since hypophysectomy in the pancreatectomized dog also reduces the blood sugar.

In view of these clinical and experimental observations on the effect of the natural estrogens on the blood sugar of the diabetic, it was interesting to determine whether stilbestrol also reduces the insulin requirement of diabetic patients. The following case histories summarize the observations made during the treatment of four frankly diabetic, climacteric women with the substance:

CASE 1.—B. S., aged 54, who had diabetes and hypertension for many years, failed to stabilize on a restricted diet and 10 units of insulin daily for two months. The oral administration of 5 mg. of stilbestrol daily for a period of six weeks eliminated the need of insulin and reduced the average blood sugar level from 180 to 123 mg. However, the marked glycosuria persisted. The hypodermic administration of 1 mg. of

in weight. Because of her limited diet, the fasting blood sugar was only 140 mg. and the urine was free from sugar. Physical examination revealed nothing abnormal other than underweight. The patient was put on an unrestricted diet and was given 5,000 rat units of estradiol benzoate (equivalent to 50,000 international units of estrone) hypodermically twice weekly until April 1, 1939. She gained 12 pounds (5.4 Kg.) and was relieved of all symptoms. Her blood sugar on repeated examinations showed a normal level, and the urine was free from reducing substance and ketone bodies.

A complete laboratory study (case 29, table 8) on April 1, 1939 preliminary to the administration of stilbestrol showed no abnormalities aside from a slight hypercholesterolemia. From April 2, 1939 to March 26, 1940 she received 1 mg. of stilbestrol hypodermically twice weekly, equivalent in terms of the international unit of estrone to the dose of estradiol

* Patient vomited.

stilbestrol every fourth day and 10 units of insulin daily for a period of three months maintained her blood sugar at a normal level with only an occasional spill of sugar in the urine.

CASE 2.—S. A., aged 48, complained of flushes, weakness, pruritus vulvae, interdigital dermatitis, insomnia and fatigue. Complete blood studies showed 192 mg. of sugar and 240 mg. of cholesterol. All other values were normal. The urine showed only a trace of sugar and no acetone. She was given orally from 3 to 15 mg. of stilbestrol daily and an unrestricted diet for a period of three months, during which time a gradual reduction in the hyperglycemia and complete relief of the symptoms occurred. Another complete study done at the termination of treatment showed a reduction of 70 mg. in the sugar and of 54 mg. in the cholesterol (case C5, table 8).

CASE 3.—M. D., aged 57, who had diabetes and who was maintained relatively free from hyperglycemia by a rigid diet for several years with a resultant severe weight loss, was first seen by us in September 1938. She complained of marked weakness, nervousness, hot flushes, sweats and excessive loss

benzoate she had previously received. During the year of treatment there was complete freedom from symptoms and hyperglycemia, but the cholesterol content of the blood remained approximately the same. Withdrawal of the stilbestrol on March 26, 1940, because of the appearance of malaise, nausea and epigastric discomfort, resulted in a rise of 58 mg. in the blood sugar and the appearance of marked glycosuria.

CASE 4.—D. L., aged 47, who had chronic diabetes, consulted us in the latter part of 1935 for the relief of severe menopausal symptoms. Until then her maintenance requirement of insulin had been 22 units daily. Examination showed no abnormalities other than a marked hypertension and a blood sugar of 179 mg. despite the high dose of insulin. Her urine was free from sugar and ketone bodies. Without her diet being changed, she was given 10,000 rat units of estradiol benzoate (equivalent to 100,000 international units of estrone) hypodermically twice weekly. At the end of a month, 10 units of insulin daily was sufficient to maintain the blood sugar at a normal level. During the following four years, while she was receiving varying doses of estradiol benzoate for the relief of menopausal symptoms, it was found that her insulin requirement varied inversely

with the quantity of estrogen administered. When only 2,000 rat units of estrogen was given twice weekly, she required a minimum of 15 units of insulin daily.

On March 14, 1939 stilbestrol was substituted for the estradiol benzoate. She was given 1 mg. of stilbestrol hypodermically twice weekly and 10 units of insulin daily for one year. On this regimen she remained free from hyperglycemia and glycosuria, evincing no intolerance to the stilbestrol. However, withdrawal of the insulin resulted in hyperglycemia and glycosuria. After a year's treatment with stilbestrol she developed malaise, epigastric distress and nausea without, however, showing evidence of either hepatic or renal damage (case 61, table 8).

COMMENT

It is evident from a survey of the literature and the histories of these four diabetic climacteric patients that neither the natural estrogens nor the synthetic product stilbestrol substitutes for insulin completely. When 1 mg. of stilbestrol (equivalent to 50,000 international units of estrone) is given hypodermically twice weekly, the insulin requirement is markedly decreased. There is, nevertheless, no advantage in the use of the

The untoward reactions of these 42 patients consisted mostly of nausea and vomiting. In a few, epigastric distress and abdominal pain were dominant. One patient who was given 5 mg. of stilbestrol twice daily orally had such severe epigastric pain at the start of treatment that she was removed to a hospital under the mistaken diagnosis of acute cholecystitis. Two of the 42 patients had acute dermatitis of the vulva, which may or may not have been caused by the substance. One of the group complained of a severe headache after each dose of 5 mg. given hypodermically. Another one of the group discontinued the drug because of the occurrence of trifacial neuralgia. A mild degree of nausea for a few days was complained of by 9 additional patients. It was not sufficient, however, to require discontinuation of treatment.

It must be remembered, however, that in the treatment of a large number of patients, especially of the menopausal type, over a period of many months, symptoms totally unrelated to the drug administered may appear in some of them. For instance, vertigo, pares-

estrogens, natural or synthetic, in the treatment of diabetes mellitus unless a severe menopausal syndrome coexists.

THE INCIDENCE OF TOXIC SYMPTOMS FROM
STILBESTROL IN THE HUMAN BEING

Most of the reports of clinical investigations conducted in Europe and, to a lesser degree, in this country indicate that, unlike the natural estrogens, stilbestrol produces toxic symptoms in from 5 to 80 per cent of the patients treated.¹⁴ The available reports are so overwhelmingly discordant that one is at a loss in forming an opinion as to the fitness of the product for human use. The reported toxic symptoms were in the form of nausea, vomiting, epigastric distress, abdominal pain, diarrhea, lassitude, cutaneous rashes and even acute psychotic reactions. They occurred equally in patients treated with stilbestrol by either the oral or the hypodermic route.

An analytic study of 189 patients treated with stilbestrol for conditions described in the foregoing paragraphs shows the occurrence of side-effects reasonably attributable to the administration of the substance and severe enough to require cessation of treatment of 42 of the patients (22.2 per cent).

thesias and even psychotic reactions are not uncommon among menopausal women. Should these symptoms develop during the administration of a given drug, there would be a natural tendency to correlate them as cause and effect. However, for the sake of accuracy, the appearance of all untoward symptoms in any of the 189 patients are herein credited to the drug.

There seems to exist, as pointed out by MacBryde,¹⁵ a definite relationship between the size of the dose of stilbestrol and the incidence of toxic symptoms (table 6). For example, only 1 of 31 patients (3.2 per cent) who had received from 0.2 to 0.5 mg. by mouth daily for a period of months could not tolerate the substance, whereas 9 of 51 patients (17.7 per cent) who had received 1 mg. by mouth daily were intolerant to the drug. The incidence of nausea and vomiting rose gradually with the increase in size of the dose and exceeded 30 per cent when 3 or 5 mg. was given daily by the oral route. These are, however, enormous doses, 5 mg. of stilbestrol being equal to 250,000 international units of estrone. It must nevertheless be remembered that equivalent oral doses of estradiol have never, in our experience, produced any untoward symptoms. The therapeutic effectiveness, however, of orally administered estradiol is doubtful.

14. Bishop, P. M. F.; Boycott, Muriel, and Zuckerman, S.: The Estrogenic Properties of "Stilbestrol" (Diethylstilbestrol), *Lancet* 1:5 (Jan. 7) 1939. Shorr, Robinson and Papanicolaou.⁴

15. MacBryde, Cyril M.; Freedman, Harold, and Loeffel, Ellen: Studies on Stilbestrol; Preliminary Statement, *J. A. M. A.* 113:232 (Dec. 23) 1939.

The hypodermic administration of from 0.2 to 0.5 mg. of stilbestrol every fourth day, comparable in therapeutic effectiveness to like doses given daily by mouth, also produced side effects in only 1 of 43 patients (2.3 per cent). The incidence of toxic symptoms in the hypodermically treated patients likewise gradually rose with the increase in dosage, so that the administration of 2 mg. or more every fourth day resulted in untoward reactions in as many as 52.4 per cent (table 6).

From the foregoing, it is evident that the administration of from 0.2 to 0.5 mg. daily by mouth or every fourth day hypodermically produces gastrointestinal symptoms in only 3 per cent of the patients. These small doses of stilbestrol, representing a potency of from 10,000 to 25,000 international units of estrone, are, however, insufficient for many patients suffering from the menopausal syndrome. If larger doses of estrogen are necessary, stilbestrol cannot and should not be employed because of the high incidence of untoward reactions.

That the gastrointestinal symptoms evoked by the administration of large doses of stilbestrol are of central origin is evident from the fact that the hypodermic administration of comparable doses produces a higher incidence of such symptoms than the oral administration does (table 6).

The time of appearance of toxic symptoms varied somewhat with the mode of administration. They appeared within a day or two of the beginning of treatment in 27 of the 32 patients who were intolerant to the oral administration of stilbestrol but appeared much later in 8 of the 10 who were intolerant to the hypodermic administration of the substance (table 7).

THE POSSIBILITY OF TISSUE DAMAGE FROM STILBESTROL IN THE HUMAN BEING

Clinical observations limited to general physical examination, urinalysis and hemoglobin estimations at regular intervals failed to reveal changes in any of the 139 patients who received stilbestrol for periods varying from one to fourteen months or in any of the 42 patients who showed early or late intolerance to the substance. The 8 puerperal patients who received stilbestrol for only a few days are not included here.

An exhaustive clinical and laboratory study before and after treatment of 10 patients who received total doses of from 35 to 825 mg. of stilbestrol—an average of 274.9 mg. for each patient—likewise failed to show definite evidence of tissue damage. The laboratory studies in each of these 10 patients included determination of the basal metabolism, complete blood count, bleeding and coagulation times, hippuric acid excretion for liver function, urinalysis, alkali reserve and the content in the blood of sugar, urea nitrogen, creatinine, uric acid, chloride, cholesterol, calcium, phosphorus, total protein, albumin and globulin (table 8).

In 2 of these 10 cases (29 and 61, table 8), exhaustively studied before and after a course of treatment with 1 mg. of stilbestrol hypodermically twice weekly, toxic symptoms developed at the end of a year's treatment. The final studies, at this time, showed no significant alterations. Nevertheless, several subsequent attempts to administer stilbestrol in like manner promptly resulted in recurrence of the nausea and epigastric discomfort.

A perusal of table 8 will show a significant shift in the blood cholesterol of 2 patients. Whether or not this was caused by the medication is problematic.

THE EFFECTS OF STILBESTROL ON THE VITAL ORGANS OF RATS AND RABBITS

As seen in table 9, the daily injection of 75 micrograms, or approximately 0.5 microgram per gram of body weight, of stilbestrol for a period of forty-two days in rats resulted in cloudy swelling and congestion in the liver and kidneys, and in the deposit of pigment in the spleen which indicates excessive blood destruction. Daily injections of 1,500 micrograms of stilbestrol, or approximately 0.5 microgram per gram of body weight, for a period of forty-two days in rabbits also produced cloudy swelling of the liver, kidneys and spleen. Larger doses in both species caused severer tissue damage in the form of necrosis. Doses smaller than 0.5 microgram per gram of body weight, given over long periods, produced no discernible changes in the vital organs of the rabbit (table 9).

It therefore seems that both the rat and the rabbit are almost equally susceptible to stilbestrol and that the damaging dose in both species is approximately 0.5 microgram per gram of body weight. It should be remembered however that, as small as these doses seem in terms of weight, the 75 micrograms given daily to the rats represent, in terms of estrogenic potency, 375 rat units or 3,750 international units of estrone. Similarly, the 1,500 micrograms given daily to the rabbits represent 7,500 rat units or 75,000 international units of estrone. It must, moreover, be remembered that even the natural estrogens when given in much larger doses also produce tissue damage in the experimental animal.¹⁶

From these experimental observations on the toxicity of stilbestrol per gram of body weight of the rat and rabbit, a woman weighing 150 pounds (68 Kg.) would theoretically sustain no tissue damage from the daily hypodermic administration of 30 mg. of stilbestrol. However, as shown in the preceding paragraphs, the susceptibility of the human being to the substance is quite apparent, since as little as 2 mg. given parenterally every fourth day produced toxic side effects.

CONCLUSIONS

The clinical and experimental observations on stilbestrol herein recorded justify the following conclusions:

1. Stilbestrol is a highly effective estrogen when administered either orally or hypodermically. The ratio between the effective oral and hypodermic doses is 5 to 1 in the human being as well as in the rat.
2. In women who can tolerate stilbestrol, it produces all the therapeutic effects obtainable with the use of the natural estrogens.
3. Stilbestrol is highly toxic as compared with the natural estrogens, evoking nausea, vomiting, epigastric pain and malaise in 52.4 per cent of patients who receive 2 mg. (equivalent to 10,000 rat units) hypodermically every fourth day. Given orally at this dosage level, the incidence of toxicity is considerably less (21.3 per cent).
4. Stilbestrol may be safely administered in doses not exceeding 0.5 mg. daily by mouth or every fourth day hypodermically. At this dosage level the incidence of nausea and vomiting is only 3 per cent.
5. Tissue damage in the human being resulting from the administration of relatively large doses of stilbestrol,

16. Selye, Hans: On Toxicity of Estrogens with Special Reference to Diethylstilbestrol, *Canad. M. A. J.* 41:48 (July) 1939.

given over a long period of time, is not demonstrable by physical examination and the laboratory means at our disposal.

6. In the rat and the rabbit, the daily administration of as little as 0.5 microgram of stilbestrol per gram of body weight produces cloudy swelling and congestion in the liver and kidneys. Larger doses produce necrosis of the liver, kidneys and adrenal glands of these species.

ABSTRACT OF DISCUSSION

DR. THEODORE NEUSTAEDTER, New York: I am unable to discuss the intramuscular injection of stilbestrol, for my associates and I have confined ourselves solely to the oral administration of the drug. Our series of menopausal cases numbers 54. These have been treated for a minimum period of six months or more. Our series is larger, but treatment of these hasn't as yet extended over a period of six months. The dosage has varied from 0.1 to 5 mg. three times daily. In this group there were 5 cases of nausea and vomiting, 6 cases of slight nausea which disappeared when the dosage was reduced, 1 gastric upset, 1 case of drowsiness and dizziness and 1 of abdominal distress. On the whole the toxic effects so far have not been especially serious. Peculiarly enough our results, as far as the increase of the size of the dose, are not in accord with the authors', since there are patients who require as much as 15 mg. daily, who tolerate the dose well and whose symptoms are well controlled. The vaginal smear is no indication of symptomatic improvement. I agree with the authors' results. The effectiveness of oral administration is in striking contrast to the use of estrogen by mouth. Larger dosage of estradiol orally is required to produce the particular changes in the endometrium. In some instances, after the withdrawal of therapy, bleeding—which is similar to that found after withdrawal of estradiol—has occurred. The authors report 68 per cent of cases with marked relief. We have found as high as 85 per cent marked relief of the menopausal symptoms with stilbestrol. Possibly when our series is as large as theirs this percentage may be lower. This slide shows the stimulation of a definite follicular effect with a small dose, something we cannot do orally with estradiol or any of the estrogens in small amount.

DR. L. M. RANDALL, Rochester, Minn.: The authors should be commended on this survey of an important situation. All realize the need for an estrogenic substance that can be administered effectively, economically and safely by mouth. Ample evidence exists to prove the estrogenic effectiveness of stilbestrol, and apparently the expense of therapy would be greatly reduced were it generally available. We are now interested chiefly in the safety factor. Dr. Mazer and his colleagues state that 22.2 per cent of all patients who received stilbestrol manifested toxic symptoms that resulted in the cessation of treatment; 17.7 per cent of these patients received a dose of 1 mg. of stilbestrol. It may be noted, however, that the authors gave the patients the benefit of doubt and probably included untoward symptoms that perhaps could not be attributed to the stilbestrol. Their extensive laboratory examination of a group of patients did not indicate any evidence of damage to bodily tissues as far as these tests were able to detect them. One may point out that as yet there is no workable knowledge concerning the metabolism of stilbestrol in the body. Engel has indicated that this substance is not conjugated in the liver; hence one may not take the negative results of these tests too literally. At any rate, it seems reasonable to state that if toxic symptoms do not appear one may safely administer stilbestrol over a long period of time with no detectable evidence of tissue damage. Nor can one yet be certain that some patients may not be encountered who have idiosyncrasies to stilbestrol. One has had experience with cinchophen and dinitrophenol that should make one a little cautious. At the Mayo Clinic we have treated approximately 72 patients in the last fourteen months with doses up to 1 mg. of stilbestrol daily. This may have been administered in divided doses or as a single dose. These patients have been practically all those in whom we were treating menopausal symptoms. In our experience the percentage of toxic symptoms has been less than 5 per cent, corresponding closely to those of Dr. Neustaedter. When the dose has been increased to more than 1 mg. a day the

percentage of toxic symptoms has rather sharply increased. Such investigations as reported here, coupled with our experience, lead us to plan to continue with no greater than a 1 mg. dose a day. A substance that has as high an incidence of toxic effects should be used with some circumspection.

DR. A. A. HEROLD, Shreveport, La.: I should like to ask the authors to explain one feature which they brought out, and that is their reference to the beneficial effect on diabetes of this preparation. I notice that they mentioned the fact that large doses were followed by destruction of the adrenals and I wonder if that explains the beneficial effect on the diabetes.

DR. CHARLES MAZER, Philadelphia: The reduction in the blood sugar of diabetic patients by the administration of the natural estrogens or stilbestrol is apparently through inhibition of the diabetogenic hormone of the anterior pituitary lobe. In the depancreatized dog the daily administration of 200 units of estrogen reduces the blood sugar considerably. In diabetic patients we have likewise seen marked reduction in the blood sugar and the insulin requirement when the natural or the synthetic estrogens are administered in adequate doses. That the reduction of the blood sugar in diabetic patients is not through inhibition or destruction of the adrenal cortex is evident from the fact that none of them showed any symptoms of adrenal insufficiency. It would be safe to put stilbestrol on the market if the individual dose were not to exceed 0.5 mg., given either daily orally or every fourth day hypodermically. However, physicians are prone to use large doses, which may produce indiscernible tissue damage. Our means of determining mild tissue damage in the human being are still not all one may desire. Animals, however, show definite evidence of necrosis at the dosage level of 0.5 microgram daily per gram of body weight.

SODIUM PERBORATE OINTMENT AND POISON IVY DERMATITIS

BEDFORD SHELMIRE, M.D.

DALLAS, TEXAS

A recent article in *Public Health Reports*¹ discussed editorially in *THE JOURNAL*² recommends a vanishing cream containing a nonirritating, nonstaining oxidizing agent, such as 10 per cent sodium perborate, as an effective preventive against poison ivy dermatitis. The oxygen liberated by the perborate ointment was said to detoxify the highly allergenic ivy oleoresin. The publicity accorded this new preventive will undoubtedly give many ivy sensitive subjects a false sense of security and result in instances of widespread dermatitis in credulous individuals.

The very stable dermatitis producing fraction of the oleoresin of poison ivy decomposes and becomes inert slowly, if at all, in the presence of large amounts of free oxygen. In my hands this recommended ointment has afforded no greater safeguard against poison ivy dermatitis than has calamine or zinc oxide in vanishing cream, zinc oxide ointment or plain petrolatum, all of which offer only slight mechanical protection.

Since McNair in 1923³ stated that the milky juice of poison ivy turns black on exposure to the air and thereby loses its toxic properties, physicians have attempted to find some oxidizing agent which would quickly render inert the dermatitis producing sap of this plant. The action of the neutralizing agent must

The persons tested in these experiments have been observed in repeated attacks of clinically acquired poison ivy dermatitis. They are regularly employed by me as patch test subjects and paid from a grant by Eli Lilly & Co. for the study of poison ivy sensitivity.

2. Poison Ivy Dermatitis, editorial, *J. A. M. A.* 115: 862 (Sept. 7) 1940.

3. McNair, J. B.: *Rhus Dermatitis: Its Pathology and Chemotherapy*, Chicago, University of Chicago Press, 1923.

be rapid, since poison ivy dermatitis cannot be prevented if the sap is left in contact with the skin for longer than a few minutes before being removed thoroughly by cleansing with soap and water, ether, acetone and other solvents.⁴

Little was known about patch testing and allergic cutaneous reactions at the time McNair made his statement that the black ivy sap is nontoxic. He apparently formed his erroneous conclusion that the black oxidized sap is nonantigenic because of the absence of irritative rather than lack of true allergic cutaneous reactions.

EXPERIMENTAL STUDY

The fresh milky sap of the poison ivy plant is a marked cutaneous irritant for both man and animal. On exposure to the air this sap turns into a black gummy substance which on aging becomes very hard and slowly loses the greater part of its irritative quality but seems to retain all, or the major portion, of its antigenic potency.

A small drop of the milky juice expressed from the broken end of the petiole of a poison ivy leaf was placed in an open glass container. The sap rapidly became brownish black. After exposure to the air for two months the black, brittle, shellac-like, match-head sized film on the glass was partially dissolved by the addition of 1 ounce (30 cc.) of acetone. Frankly vesicular patch reactions were evoked when the latter material was dropped on the skin of ivy sensitive persons. Control tests were negative.

The trunks of two species of poison ivy (*Toxicodendron radicans* and *T. quercifolia*) were blazed with a knife. One week later the black oxidized gummy exudates were carefully collected with a small knife blade, and match-head sized portions were placed in glass containers. After standing exposed to the air for three months the small firm masses were partially dissolved in 1 cc. of ether. When this ether, which contained the soluble dermatitis producing fraction of the sap, was diluted one thousand times with acetone and applied to the skins of ivy sensitive persons, frankly vesicular patch reactions were evoked.

Leaves of the poison ivy plant were crushed between small squares of cotton cloth. Presence of the oleoresin on the cloth was indicated by the black stains which appeared on the squares half an hour later. After storage in open glass containers at room temperature for one year, these squares proved highly allergenic for ivy sensitive persons when moistened with ether and used for patch test material.

The black, oxidized sap of poison ivy is therefore highly potent and not inert as originally stated by McNair.

One cc. of oleoresin extracted from ivy leaves was dissolved in 10 cc. of ether. This mixture was poured into a pint fruit jar, 1 ounce (30 Gm.) of powdered sodium perborate added and the jar half filled with tap water. After thorough shaking, the jar top was removed and the mixture allowed to stand exposed to the air. During the next five days 5 additional ounces of perborate was added to the jar. Almost continuous bubbling of the mixture indicated the liberation of large amounts of free oxygen. After standing for an additional twenty-four hours, ether was added and the mixture thoroughly agitated. The supernatant greenish ether was separated from the underlying water and

perborate by separatory funnel. On evaporation of the ether a dark green, gummy mass remained. When diluted ten thousand times with acetone, this material evoked frankly positive patch reactions on ivy sensitive persons. Large amounts of sodium perborate had certainly not rendered the ivy oleoresin inert during a contact period of seven days. Like results were obtained when ivy oleoresins extracted from the bark of branches and from roots were similarly treated with large amounts of perborate.

Saturated solutions of sodium perborate were then mixed with equal parts of 1:100 ether dilutions of ivy oleoresins obtained from leaves, bark and roots. Additional perborate was added at intervals to insure the almost continuous liberation of free oxygen. After standing for two weeks, ether was added to restore the oleoresins to the 1:100 dilution. Patch tests with the three solutions evoked intense vesicular reactions on persons clinically sensitive to poison ivy.

Five drops of ivy oleoresin extracted with ether from freshly gathered ivy leaves were placed in 1 ounce of freshly prepared 10 per cent sodium perborate in vanishing cream. After thorough stirring, the mixture was allowed to stand for one week, a few drops of water and a small amount of sodium perborate being added daily to assure the almost continuous liberation of oxygen. Patch tests with this cream evoked frankly vesicular patch reactions on ivy sensitive persons.

Five drops of the fresh milky sap of poison ivy were placed in 1 ounce of a freshly prepared 10 per cent perborate cream. Water and perborate were similarly added for seven days. Intense reactions were evoked when this cream was then rubbed on the skins of ivy sensitive persons. No reactions were elicited when the cream was similarly applied to nonsensitive controls.

Two cc. of acetone was placed in a 10 cc. glass vial and 1 drop of the fresh milky juice from a broken ivy leaf petiole dropped in the vial and the solution thoroughly agitated. After standing for one week, 2 cc. of water and 1 Gm. of powdered sodium perborate were added. Bubbling of the mixture indicated liberation of free oxygen. After standing for twenty-four hours, 2 cc. of hydrogen peroxide and a small piece of decaying meat were added to the vial. Foaming of the mixture indicated the liberation of large amounts of free oxygen. One cc. of ether was then added to replace the partially evaporated acetone. After thorough agitation the supernatant ether was removed with a pipet. This material evoked frankly vesicular patch reactions on ivy sensitive volunteers. Large amounts of free oxygen had failed to detoxify 1 drop of the fresh milky sap of the ivy plant. This experiment was repeated with drops of milky sap from the three recognized species of poison ivy (*Toxicodendron radicans*, *T. quercifolia* and *T. diversiloba*), all of which are cultivated in my own back yard.

Linear areas of the backs of persons sensitive to ivy were liberally smeared with plain petrolatum, zinc oxide ointment and 10 per cent sodium perborate, 10 per cent calamine and 10 per cent zinc oxide in vanishing cream. One-half hour later the treated sites and untreated cutaneous areas were patch tested with ivy oleoresin diluted one thousand, five thousand and ten thousand times with acetone. There was no demonstrable reduction in the cutaneous reactions at the treated sites. Areas of untreated skin were then painted with the various dilutions of ivy in acetone and the sites liberally covered

4. Shel mire, Bedford: Contact Dermatitis from Weeds: Patch Testing with Their Oleoresins, J. A. M. A. 113: 1085 (Sept. 16) 1939.

with the various ointments and creams. The protective coverings did not lessen the cutaneous reactions, as vesiculation occurred at all the tested sites.

Areas of skin were similarly smeared with the five protective ointments. One-half hour later 1 drop of a mixture of poison ivy oleoresin diluted one thousand times with corn oil was placed on the treated areas with a medicine dropper and the sites were covered for twenty-four hours with gauze dressings. Erythema, swelling and vesiculation occurred at the tested sites. These reactions were but slightly less than those evoked on untreated areas of skin with the same dilutions of the ivy oleoresin in corn oil. These tests were repeated six times with similar results on one person, the thighs, abdomen, chest and back being used for test sites.

Clinical ivy dermatitis is usually acquired either by direct contact with the sap which exudes from the injured vascular bundles of the ivy leaves and broken leaf petioles or indirectly from contact with sap contaminated objects as fingers, tools or clothing. Extremely sensitive persons can handle the uninjured ivy plant with absolute impunity.⁵

Separate areas of the skin of the back, legs and forearms of ivy sensitive persons were smeared with 10 per cent sodium perborate, 10 per cent calamine and 10 per cent zinc oxide in vanishing cream. After allowing for evaporation of the water in the creams, the treated areas were stroked with the broken ends of ivy leaf petioles. In all instances a vesicular dermatitis resulted from this massive exposure.

Control and similarly treated areas were then gently stroked with a crushed ivy leaf or rubbed with my contaminated fingers. Reactions at the sites covered with the perborate creams were only slightly less than those evoked on untreated areas of skin. Reactions over sites treated with the inert calamine and zinc oxide creams were frequently more reduced. The calamine and zinc oxide treated areas left a more adherent, powdery film than did the sites smeared with the perborate cream.

Difficulty was experienced in obtaining a perborate cream which would adhere to the skin. Within ten or fifteen minutes after application of the cream the powdery film would flake off the treated site. With some creams the flaky, powdery residue could be blown off with the breath. Almost the entire film would brush off with one stroke of the hand. Ten per cent perborate powder in vanishing cream was then purchased at five different drug stores. Portions of these creams were liberally smeared on the arms of four children. One-half hour after resuming ordinary play, only a trace of the protective films remained at the treated sites.

CONCLUSION

Ten per cent perborate ointment offers little protection against poison ivy dermatitis. The amount of protection afforded seems directly proportionate to the thickness of the powdery film left after evaporation of the water of the vanishing cream. That this partial protection is entirely mechanical and not due to detoxification of the oil by the perborate is indicated by the fact that the oleoresin of poison ivy deteriorates slowly, if at all, in the presence of liberal amounts of free oxygen and because of the fact that inert zinc oxide or calamine in vanishing cream affords equal protection against ivy dermatitis.

SULFAPYRIDINE AND SULFATHIAZOLE THERAPY IN PNEUMOCOCCIC PNEUMONIA

HARRISON F. FLIPPIN, M.D.

JOHN G. REINHOLD, Ph.D.

AND

LEON SCHWARTZ, M.D.

WITH THE COLLABORATION OF JEFFERSON H. CLARK, M.D.,
AND S. BRANDT ROSE, M.D.

PHILADELPHIA

In an attempt to evaluate the comparative therapeutic effectiveness and toxicity of sulfapyridine and sulfathiazole, pneumonia patients admitted to the medical services¹ at the Philadelphia General Hospital were divided into therapeutic groups so that approximately an equal number received sulfapyridine and sulfathiazole.² This report deals with the study of 400 adult patients, the first 200 consecutively typed pneumococcal pneumonia patients from each therapeutic group. Included in this group of 400 patients are 200 who formed the basis of a previous report.³ A representative group of patients (50 treated with sulfapyridine and 56 with sulfathiazole) was studied in somewhat greater detail by laboratory methods. Our purpose in this paper is to compare the behavior and activity of the two drugs when employed in the treatment of pneumonia.

ROUTINE MANAGEMENT

As soon as the clinical diagnosis of pneumonia was established and specimens for routine laboratory studies (blood, urine and sputum) were collected, chemotherapy was begun. An initial dose of 3 Gm. of either drug by mouth was followed by 1 Gm. of the drug every four hours—unless severe signs of toxicity developed—until the temperature remained normal for forty-eight hours and the patient showed evidence of clinical improvement. The initial 3 Gm. dose was repeated in four hours in the sulfathiazole scheme of dosage in order to compensate in part for the more rapid excretion of the drug. In general, the total dosage of either drug was from 25 to 35 Gm. In certain instances, when a rapid elevation of the blood level was desired, a 5 per cent solution of sulfapyridine sodium or sulfathiazole sodium (0.06 Gm. per kilogram of body weight) in sterile distilled water was given intravenously as a supplement to oral therapy. Patients in both therapeutic groups received either sodium bicarbonate or sodium citrate in amounts equal to that of the drug. The purpose of alkali administration was to aid in maintaining solubility of excreted drug by keeping the reaction of urine near neutral. All patients were given at

Read before the Section on Pharmacology and Therapeutics at the Ninety-First Annual Session of the American Medical Association, New York, June 13, 1940.

Owing to lack of space, this article has been abbreviated in THE JOURNAL by omission of tables and a chart. The complete article appears in the authors' reprints.

Dr. Walter J. Crocker, chief of the Division of Clinical Pathology of the Laboratories of the Philadelphia General Hospital, cooperated with the authors in this work, and technical assistance was given by Miss Shlomith Bethlany and Miss Beatrice Doak, who were detailed for this and related studies on pneumonia by the Pennsylvania State Department of Health, Division of Pneumonia Control.

1. Clinical facilities were given us for this study by the following chiefs of service: Drs. R. S. Boles, H. D. Jump, Thomas Klein, D. W. Kramer, S. A. Loewenberg, the late David Riesman, W. E. Robertson, H. W. Schaffer, T. G. Schnabel and the late R. G. Torrey.

2. Dr. George A. Harrop, Squibb Institute for Medical Research, New Brunswick, N. J., supplied the sulfathiazole used in this study.

3. Flippin, H. F.; Schwartz, Leon, and Rose, S. B.: The Comparative Effectiveness and Toxicity of Sulfathiazole and Sulfapyridine in Pneumococcal Pneumonia, *Ann. Int. Med.* 13: 2038 (May) 1940.

least 2,500 cc. of fluid during each twenty-four hour period. When sulfathiazole or sulfapyridine had apparently failed to bring about a favorable clinical response within from thirty-six to forty-eight hours, the patient was usually given specific serum.

THERAPEUTIC RESULTS: MORTALITY

In this report we have included all patients with a diagnosis of pneumococcic pneumonia who received drug therapy. In general, the sex, race, age and day of disease on which treatment was begun were comparable in the two groups. Our results show no significant difference in mortality between the two drugs (table 1).

In addition to chemotherapy, type-specific serum was given to 37 patients. Of the 21 patients who received

both sulfapyridine and serum 7 died, and of the 16 patients who received sulfathiazole and serum 6 died. This group of 37 patients includes 17 with bacteremia (11 sulfapyridine, 6 sulfathiazole) with 10 deaths (7 sulfapyridine, 3 sulfathiazole). It is our impression that the administration of serum was a deciding factor in the recovery of several patients in this combined therapy group (chart 3).

ANALYSIS OF DEATHS

Of the 52 patients who died, 14 (7 sulfapyridine, 7 sulfathiazole) died within twenty-four hours after admission. Of the remainder, 16 (10 sulfapyridine, 6 sulfathiazole) had advanced cardiovascular disease. Individual cases of active pulmonary tuberculosis and of uremia on admission were encountered in each therapeutic group. In addition, 2 sulfapyridine treated patients had delirium tremens, 1 having been admitted with a broken arm and a fractured skull. One sulfa-

pyridine treated patient was proved by autopsy to have had a bronchogenic carcinoma and in the sulfathiazole series there were patients with cerebral hemorrhage, severe diabetes mellitus and pneumonia associated with an acute surgical condition.

INFLUENCE OF TREATMENT ON THE COURSE OF THE DISEASE

The most striking clinical observation was the frequency with which the initiation of drug therapy was followed within from twenty-four to forty-eight hours by a critical drop in temperature. It is apparent that the action of sulfapyridine in lowering the temperature was more rapid than that of sulfathiazole (table 2). However, a secondary rise in temperature occurred in 44 cases (27 sulfapyridine, 17 sulfathiazole), and these

usually required further drug therapy. Since chemotherapy was continued until clinical improvement was definitely established, it is noteworthy that its average duration was practically the same, four and four-tenths and four and six-tenths days respectively for groups of patients receiving sulfapyridine and sulfathiazole. The average number of hospital days for patients in the two therapeutic groups also was the same, thirteen and four-tenths days. In estimating the average number

of hospital days, we have excluded all patients who died or who remained in the hospital because of conditions other than pneumonia.

COMPLICATIONS

The incidence of complications was low and comparable in the two therapeutic groups. Empyema developed in 5 patients (3 sulfapyridine, 2 sulfathiazole) with 1 in each therapeutic group dying. Two patients, 1 in each group, contracted endocarditis and died. Massive pleural effusion occurred in 15 cases (7 sulfapyridine, 8 sulfathiazole). Phlebitis developed in 1 patient in the sulfapyridine series, and individual patients with metastatic abscess and otitis media were observed in the sulfathiazole-treated group.

TOXIC REACTIONS

The most frequent toxic effects of both drugs were nausea and vomiting (table 3). Both symptoms appeared usually during the first twenty-four hours of drug therapy. The vomiting associated with sulfapyridine therapy was greater in frequency (60 per cent) and severity than that accompanying sulfathiazole treatment (22 per cent), a highly significant difference. Also, the severe nausea which frequently accompanied sulfapyridine medication (84 per cent) was milder and

comparatively infrequent in those patients receiving sulfathiazole (26 per cent) and was seldom experienced between attacks of vomiting. It was necessary to discontinue treatment of 8 patients receiving sulfapyridine because of severe vomiting as compared with only 1 patient receiving sulfathiazole. It is noteworthy that of those who vomited, four fifths of the sulfapyridine-treated patients and only two fifths of those treated with sulfathiazole vomited more than once or twice.

Toxic effects involving the urinary tract have presented disturbing features of therapy with both drugs. Microscopic hematuria was encountered in 10 per cent of the cases in both therapeutic groups. Gross hematuria was observed in 2 cases in the sulfapyridine group; pain in the loin, probably ureteral in origin, was also present in 2 cases in this group. In 1 this was associated with gross hematuria. After treatment with sulfapyridine or sulfathiazole, crystals presumably of the drugs or of derivatives occasionally have been observed in the urine. In a case of endocarditis terminating fatally, crystals of acetylsulfathiazole in the pelvis and tubules of both kidneys were found at autopsy. Despite these renal complications acute nephritis accompanying pneumonia is not necessarily a contraindication for drug therapy (chart 1).

Blood urea nitrogen (chart 6) showed no distinct trend during chemotherapy and no significant difference between sulfathiazole and sulfapyridine. Likewise, no difference in incidence or trend of oliguria was seen (chart 6). Hyposthenuria was observed with greater

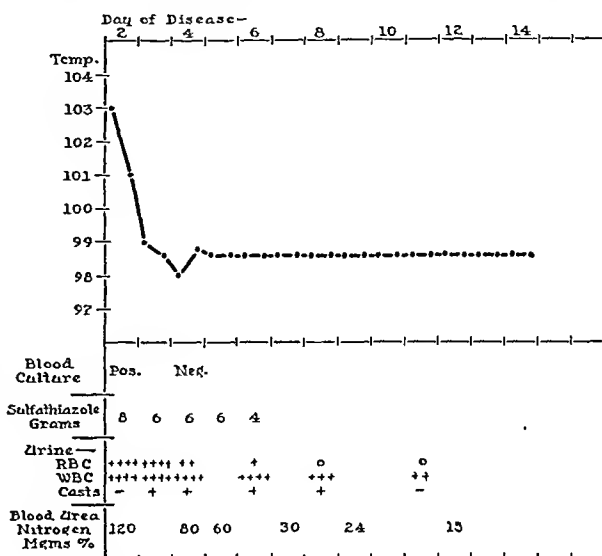

Chart 1 (A. M., a white youth aged 15).—Type VI pneumococcal pneumonia with acute nephritis and bacteremia on admission.

frequency in cases in the sulfathiazole group, but this finding is offset by its higher incidence in this group when therapy was started (chart 6).

Dermatitis, apparently caused by the administration of these drugs, was noted in 3 cases (2 maculopapular and 1 urticarial) in the sulfapyridine group and in 5 cases (3 maculopapular and 2 urticarial) in the sulfathiazole group. One patient treated with sulfathiazole showed mild conjunctivitis associated with a drug rash (purplish red subcutaneous nodules) and joint pain.

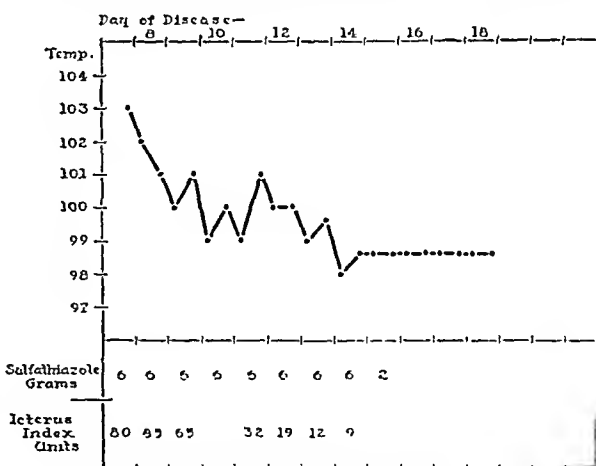

Chart 2 (W. C., a Negro man aged 49).—Type IV pneumococcal pneumonia with acute hepatitis on admission.

This complication appeared to be similar to lesions described by Haviland and Long.⁴

The question of drug fever is difficult to evaluate in pneumonia patients, although 14 patients (9 sulfa-

4. Haviland, J. W., and Long, P. H.: Skin, Conjunctival and Scleral Reactions in the Course of Therapy with Sulfathiazole, *Bull. Johns Hopkins Hosp.* 66: 313 (May) 1940.

pyridine, 5 sulfathiazole) apparently showed this condition. Also, psychosis is difficult to attribute to the use of chemical agents in an acutely febrile disease such as pneumonia. However, we have encountered 25 patients (16 sulfapyridine, 9 sulfathiazole) whose symptoms may have been due to the drug.

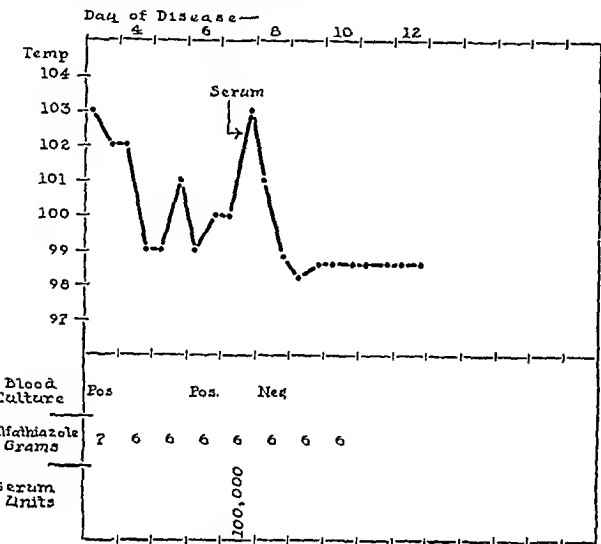

Chart 3 (J. F., a white man aged 39).—Type XIV pneumococcal pneumonia with bacteremia treated with sulfathiazole plus serum.

Repeated blood studies showed little evidence of a marked reduction in hemoglobin, red blood cell or white blood cell count that could be attributed to either drug. There were no cases of hemolytic anemia or agranulocytosis in either group, although a relative granulopenia (less than 50 per cent polymorphonuclear cells) was encountered in 3 cases in the sulfapyridine group and in 2 in the sulfathiazole group. In the majority of cases the white blood cell count tended to drop during the first forty-eight hours, coincident with the drop in temperature in both groups. Average white blood cell counts at the beginning and end of therapy made on a representative group of patients are shown in chart 6. White blood counts below 5,000 were noted in 16 cases (10 sulfapyridine, 6 sulfathiazole). The red cell count and hemoglobin likewise fell in a number of cases, but in view of the marked dehydration of most of our patients on admission it has been difficult to evaluate this apparent secondary anemia. Actually, little change in hemoglobin concentration occurred in the group as a whole (chart 6); however, some evidence of a negative correlation (correlation coefficient = -0.31) was observed between hemoglobin and free sulfathiazole. A similar relationship was not significant in the case of sulfapyridine.

We have not encountered in this series hepatitis caused by sulfapyridine or sulfathiazole, although a number of patients showed clinical or subclinical jaundice as a complication of pneumonia. While jaundice has been regarded by many as a contraindication to therapy with sulfapyridine, our experience with jaundice due to pneumonia does not support this view. Daily measurement of the icteric index of 50 patients treated with sulfapyridine and 56 treated with sulfathiazole gave average values of 10 or higher in 9 and 13 patients respectively. The mortality, temperature response or toxic manifestations of these patients did not differ from other patients suffering with pneumonia. Chart 6 shows that during the course of the illness

there was a tendency for the icteric index first to rise and then to fall to less than the initial value. The decrease occurred before drug treatment was terminated. Chart 2 shows the response to sulfathiazole administration of a patient with clinical jaundice accompanying pneumonia.

CORRELATION BETWEEN BLOOD LEVELS AND CLINICAL MANIFESTATIONS

As already stated, a group of 106 patients (50 sulfapyridine, 56 sulfathiazole) has been studied in greater detail by laboratory methods. Conclusions concerning the influence of variations in the concentration of either drug in the blood are based on this group. The concentrations of free and conjugated drug in the blood, blood urea nitrogen, hemoglobin and icteric index were determined daily. Blood was collected between 10 and 11 a. m., from one to two hours after the previous dose of drug had been given. The results are summarized in tables 4 and 5 in the form of mean values. Concentrations of the drug fluctuated from day to day in individuals but in the absence of renal involvement tended to conform to a norm characteristic for that individual. Methods employed were those listed in an earlier paper,⁵ except that the method of Bratton and Marshall⁶ was employed for sulfapyridine and sulfathiazole determinations. Recovery of sulfathiazole added to blood has ranged between 90 and 100 per cent, and the method has proved to be satisfactory and reliable for determination of this substance in both free and acetylated form.

BLOOD CONCENTRATION OF SULFAPYRIDINE AND SULFATHIAZOLE

Patients receiving sulfapyridine showed appreciably higher concentrations of both free and acetylated drug

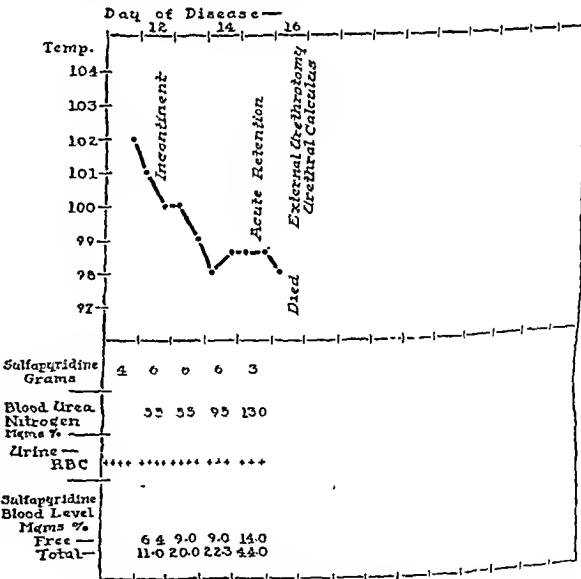

Chart 4 (H. F., a Negro man aged 49).—Type VI pneumococcal pneumonia with obstructive uropathy.

in blood than did patients receiving equivalent amounts of sulfathiazole. The average concentration of free sulfapyridine as shown by daily determinations during

5. Reinhold, J. G.; Flippin, H. F., and Schwartz, Leon: Observations on the Pharmacology and Toxicology of Sulfathiazole in Man, *Am. J. M. Sc.* 199: 393 (March) 1940.
6. Bratton, A. C., and Marshall, E. K., Jr.: A New Coupling Reagent for Sulfanilamide Determination, *J. Biol. Chem.* 128: 537 (May) 1939.

the entire period of treatment was 8.20 mg. per hundred cubic centimeters with a standard deviation of ± 3.22 , compared with an average concentration of free sulfathiazole of 5.56 mg. per hundred cubic centimeters with a standard deviation of ± 2.95 .

Studies of the behavior of sulfathiazole fed to mice and monkeys⁷ suggested that the drug was conjugated with the acetyl radical to a lesser degree than sulfapyridine. Long⁸ stated that this was true also in man. In an earlier paper⁵ we were unable to arrive at a definite conclusion concerning the differences in conjugation between the two drugs. The question has been reexamined in the course of the present study. Under identical conditions, patients receiving sulfapyridine showed an average concentration of 3.95 mg. per hundred cubic centimeters of acetylsulfapyridine with a standard deviation of ± 2.14 , while those receiving sulfathiazole showed 2.41 mg. per hundred cubic centimeters of acetylsulfathiazole with a standard deviation of ± 2.05 . The average proportion of total drug acetylated was almost identical, 32.5 per cent of sulfapyridine and 30.3 per cent of sulfathiazole. Because of the possibility that impaired renal function was influencing the extent of acetylation and observing a more characteristic relationship, a similar comparison was made in which only those patients showing no evidence of kidney damage were represented. The average proportion of drug acetylated differed little from that in the entire series, 30.4 per cent of sulfapyridine and 26.2 per cent of sulfathiazole being present as acetyl compounds in groups of 24 and 21 patients respectively.

An important difference between the two drugs is that concentration of acetylsulfathiazole is closely related to that of free sulfathiazole (coefficient of correlation = 0.56), whereas no relationship is demonstrated between free and acetylsulfapyridine (coefficient of correlation = 0.14). Administration of sulfapyridine over a period of several days often led to a moderate increase in concentration of acetylsulfapyridine in blood (chart 7). Under similar circumstances the concentration of acetylsulfathiazole tended to decrease slightly. Substitution of sodium citrate for sodium bicarbonate as a source of alkali was without influence on acetylation.

Both drugs showed correlation of a highly significant degree between blood urea nitrogen and acetylsulfapyridine and acetylsulfathiazole (coefficients of correlation = 0.69 and 0.81 respectively). Correlation between free sulfathiazole and blood urea nitrogen was less evident, whereas no relationship between urea nitrogen and free sulfapyridine was demonstrated. Accumulation in the blood of free and acetylated fractions of both sulfapyridine and sulfathiazole as an accompaniment of impaired kidney function is clearly illustrated by the record of a patient suffering from chronic nephritis (chart 5). Likewise, inability to maintain an adequate output of urine (chart 4) was accompanied often by a rise in drug concentration. Stewart, Rourke and Allen⁹ have demonstrated that the liver is the site of acetylation, although we have found little evidence of diminished conjugation in patients with increased serum bilirubin. Presumably impairment of liver function was not sufficiently severe to cause measurable changes.

RELATIONSHIP OF BLOOD LEVEL TO THERAPEUTIC RESPONSE

The optimal blood concentration for the treatment of pneumonia has not been established conclusively. In an earlier paper we¹⁰ observed a satisfactory therapeutic response over a wide range of blood sulfapyridine concentrations. Long and Bliss¹¹ have advocated blood concentrations of from 4 to 6 mg. per hundred cubic centimeters for effective therapy of moderately ill patients, although recommending higher levels (from 7 to 10 mg. per hundred cubic centimeters) in cases

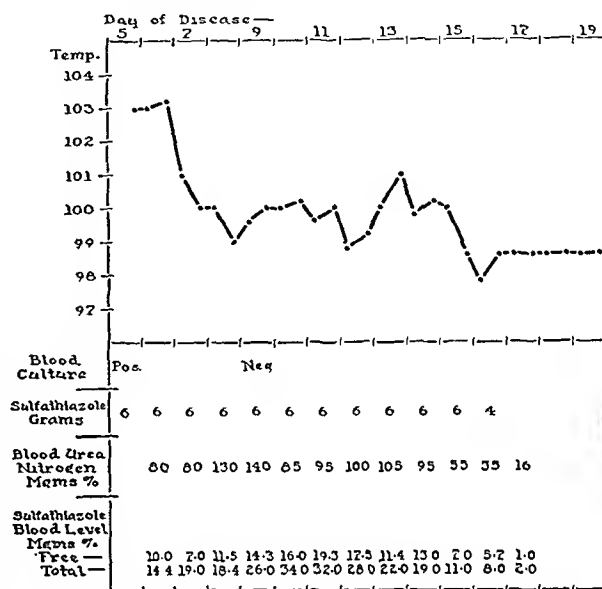

Chart 5 (L. S., a Negro man aged 50).—Type IV pneumococcal pneumonia with chronic nephritis and bacteremia on admission.

of severe involvement. Abernethy, Dowling and Hartman¹² have stated that a mean concentration of 6 mg. per hundred cubic centimeters or higher in the blood is desirable.

In order to evaluate the influence of drug concentration on therapeutic response, an attempt has been made to correlate the blood levels with the number of patients showing a critical drop in temperature within forty-eight hours of treatment (table 6). A similar tabulation has been made, based on a return to the normal temperature. For this purpose the concentrations of free drug found in the blood during the days preceding temperature response were averaged. Satisfactory response, judged by a critical fall, occurred at sulfapyridine and sulfathiazole concentrations ranging from less than 2 mg. to 15 mg. per hundred cubic centimeters.

When return to normal temperature was the basis for measurement, the difference between the response of patients with sulfapyridine concentrations below 6 mg. and that of those exceeding 6 mg. per hundred cubic centimeters was not significant when tested by the chi square method (Yates modification).¹³ Similarly, the

10. Flippin, H. F.; Lockwood, J. S.; Pepper, D. S., and Schwartz, Leon: The Treatment of Pneumococcal Pneumonia with Sulfapyridine, *J. A. M. A.* 112: 529 (Feb. 11) 1939.

13. Statistical Methods for Research Workers, Edinburgh, R. A. Fisher, 1936.

data in table 6 fails to show any statistically significant difference between lower and higher concentrations of sulfathiazole in inducing the return of the temperature to normal when tested by the chi square method.

RELATION OF BLOOD LEVEL TO TOXIC REACTIONS

A second consideration in establishing optimal concentrations in blood of chemotherapeutic agents is the influence of concentration on toxicity. Brown, Thornton and Wilson¹⁴ have observed a higher incidence of toxic effects when large amounts of drug were given and when high concentrations of drug occurred in blood. Distinct evidence of such a relationship was encountered in the present study and is given in tables 4 and 5.

The incidence of vomiting was higher among patients exhibiting concentrations of free sulfapyridine exceeding the mean, although the difference falls just short of statistical significance tested by the chi square method. The suggested relationship was tested further by assembling into one group all patients who received sulfapyridine and vomited. The mean concentration of free sulfapyridine in blood was 8.79 mg. per hundred cubic centimeters with a standard error of ± 0.546 . The remainder, who failed to vomit, showed a mean of 6.96 mg. with a standard error of ± 0.755 . The difference is

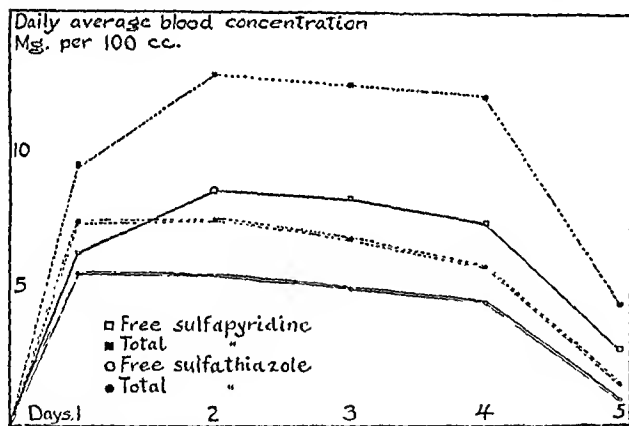

Chart 7.—Effect of oral administration of sulfathiazole (21 cases) and sulfapyridine (24 cases) for four successive days.

significant and provides evidence that higher concentrations of sulfapyridine may be a factor in vomiting. A similar relationship was less clearly demonstrated for sulfathiazole. Again, vomiting was more frequent to an extent statistically significant in patients with concentrations of sulfathiazole in blood exceeding the mean for the entire group; however, calculation of the mean concentration of sulfathiazole of those patients who vomited gave a figure that was not significantly higher than that of those who did not vomit.

Nitrogen retention (blood urea nitrogen exceeding 20) was usually accompanied by high levels of free and total sulfapyridine. While a similar association was seen less frequently for free or total sulfathiazole, the close correlation between blood urea nitrogen and concentration of acetylsulfapyridine and of acetylsulfathiazole already has been mentioned. Obviously, it is not permissible to conclude that high drug concentrations have induced nitrogen retention in these cases, although the possibility exists. The more plausible explanation is that deficient kidney function prevents rapid excretion of the drug.

A highly significant finding is the association of hematuria, either gross or microscopic, with high concentrations of acetylsulfapyridine in blood of 6 of 7 patients (chi square tested by Yates modification). The mean concentration of acetylsulfapyridine in blood of patients showing hematuria also differed from the mean of the remainder of the patients to an extent that is statistically significant. Renal or ureteral irritation caused by crystals or calculi composed of acetylsulfapyridine could explain the hematuria. Remission of hematuria and recovery occurred in all. In the sulfathiazole series the distribution of results also suggested a similar relationship between high levels of acetylated drug and hematuria. However, this was not statistically significant when tested by the chi square method, nor did the mean figures show a significant difference.

COMMENT

In our experience thus far, sulfapyridine and sulfathiazole both appeared to be effective therapeutic agents in the treatment of pneumococcic pneumonia as based on final mortality. Clinical response, as evidenced by a fall in temperature, was somewhat more striking with sulfapyridine than with sulfathiazole, although this apparent advantage had no effect on the incidence of complications and on the duration of hospitalization. Moreover, the striking frequency with which the institution of sulfapyridine therapy is followed by a critical drop in temperature within twenty-four hours may not be entirely advantageous in the light of studies *in vitro*¹⁵ showing accelerated bacteriostatic effectiveness of sulfanilamide and sulfapyridine with an increase in temperature.

In general, the more severe toxic reactions, such as serious renal involvement, blood dyscrasias and dermatitis, have been infrequent and comparable in both therapeutic groups. The hazard of severe toxic reactions increases with the prolonged use of these drugs and their use in cases of chronic organic disease complicating the acute infectious process. In the treatment of pneumonia most patients required no more than from 25 to 35 Gm. of either drug extending over a period approximating five days. We believe that this explains in part the low incidence of serious toxicity. Adequate fluid intake and the administration of alkalis are important adjuvants. It appears desirable, in order to facilitate excretion of these compounds by the kidneys, to maintain a urinary output in excess of 1,000 cc. daily.

A most troublesome and often distressing toxic effect of both sulfapyridine and sulfathiazole has been nausea and vomiting. However, vomiting has been definitely less frequent and severe in the patients treated with sulfathiazole. From the clinical point of view, this advantage is of decided importance in the management of pneumonia patients.

Administration of comparable amounts of sulfapyridine and sulfathiazole to patients suffering from pneumonia establishes appreciably higher concentrations of sulfapyridine in the blood, in part because of the more rapid rate of excretion of sulfathiazole by the kidney but mainly because sulfathiazole enters the red blood cells much less readily than does sulfapyridine.

Our data fail to demonstrate a relationship between therapeutic effectiveness and the concentration of either sulfapyridine or sulfathiazole in blood of between 2 and 15 mg. per hundred cubic centimeters. It appears that

14. Brown, W. H.; Thornton, W. B., and Wilson, J. G.: An Evaluation of the Clinical Toxicity of Sulfanilamide and Sulfapyridine, *J. A. M. A.* 114: 1605 (April 27) 1940.

15. White, H. J.: Relationship Between Temperature and Streptococcal Activity of Sulfanilamide and Sulfapyridine *in Vitro*, *J. Bact.* 38: 549 (Nov.) 1939.

therapeutic action is not enhanced by establishing concentrations of the free form of either drug exceeding 5 mg. per hundred cubic centimeters. Certain toxic manifestations occur with greater frequency as the concentration of the drug in blood increases. Thus vomiting is more prevalent at higher concentrations of either sulfapyridine or sulfathiazole. Also, high concentrations of acetylsulfapyridine in blood appear to be associated with hematuria. Therefore it should be possible to diminish the occurrence and severity of certain untoward effects by avoiding blood levels in excess of 5 mg. per hundred cubic centimeters. This conclusion applies especially to sulfathiazole, where a close dependence of acetylation on concentration of the drug in blood offers some possibility of control of the quantity of the acetylated fraction. As it is principally acetylsulfathiazole or acetylsulfapyridine that forms concretions in the urinary tract, the advantage of decreasing the amounts of the conjugated drugs requiring excretion is obvious. The greater frequency with which certain toxic effects are manifested by sulfapyridine as compared with sulfathiazole may be due in part to the higher concentration regularly attained by the former. Our results suggest that dosage on a lower scale than that widely used at this time and employed by us in this study could be used without loss of therapeutic effectiveness in the treatment of pneumonia with sulfapyridine and that certain toxic manifestations would become less frequent if this were done. It may be possible to decrease amounts of sulfathiazole also below those employed in this study. Further studies along these lines will be required.

SUMMARY

1. Two hundred adult patients with typed pneumococcal pneumonia were treated with sulfapyridine and a comparable series of 200 patients received sulfathiazole. Mortality in the two groups showed no significant difference.

2. Sulfapyridine appears to act more rapidly than sulfathiazole, as judged by a fall in temperature; however, the duration of chemotherapy, the incidence of complications and the average hospital stay were the same for the two therapeutic groups.

3. The severity and frequency of nausea and vomiting in the sulfapyridine-treated patients were significantly greater than in the patients receiving sulfathiazole. Other toxic manifestations were infrequent and comparable in the two groups.

4. The group treated with sulfapyridine showed appreciably higher concentrations of both free and acetylated forms in blood than did the group receiving equivalent amounts of sulfathiazole.

5. The average proportion of drug acetylated was the same for the two groups, but acetylation of sulfathiazole showed a close relationship to the concentration of the free drug, whereas a similar relationship was not observed for sulfapyridine.

6. Therapeutic response showed no correlation with concentrations of either drug in blood of between 2 and 15 mg. per hundred cubic centimeters.

7. Vomiting occurred more frequently at higher concentrations of free sulfapyridine. A similar relationship was demonstrated less clearly during treatment with sulfathiazole. Evidence has been obtained of a relationship between hematuria and higher concentrations of acetylsulfapyridine and possibly of acetylsulfathiazole.

ABSTRACT OF DISCUSSION

DR. HERBERT K. ENSWORTH, New York: The favorable reception which sulfapyridine has received leaves little doubt as to its efficacy in pneumococcal infection. It has, however, certain drawbacks in the form of toxic reactions. It has been hoped that some therapeutic agent would be discovered which would embody all the advantages of sulfapyridine and none of its disadvantages. Drs. Flippin, Schwartz and Reinhold have given us a report of their experience with a new drug which it was thought might fill such a bill. The evident efficacy of sulfathiazole is in their hands of the same order as that of sulfapyridine; in fact, their mortality rates in both the nonbacteremic and the bacteremic groups favor sulfathiazole slightly. The only marked advantage of sulfathiazole appears to lie in a greatly lowered incidence of nausea and vomiting, particularly of the more severe grades. During the past winter, all the pneumonia patients admitted to one of our men's medical wards at Bellevue have received sulfathiazole, and we have been able to compare the results obtained with those secured with similar groups of pneumonia patients treated simultaneously in other wards with sulfapyridine. The results of our studies confirm in the main the results at the Philadelphia General Hospital. A few of our patients have seemed to have a less dramatic fall in temperature, although their more generally favorable condition as regards the gastrointestinal tract has at least partially compensated for this. We likewise have not been able to correlate clinical response with the level of either drug in the blood. We have not thought it necessary to give more than 1 Gm. as a second dose; we have used 2 Gm. of sulfapyridine and either 2 or 3 Gm. of sulfathiazole as an initial dose. We have tried to use the smallest amount of drug consistent with satisfactory results, and we agree that the less that can be used the lower will be the incidence of untoward and particularly the more serious untoward reactions. For the uncomplicated case which responds promptly to chemotherapy we believe 16 Gm. of either drug is usually sufficient. However, it is important to give more than this to a bacteremic patient regardless of the rapidity of response. The exact relative efficiency of the two drugs will require more time to establish.

DR. E. H. LOUGHLIN, Brooklyn: The results of therapy with sulfapyridine and sulfathiazole reveal mortality rates of 11.9 and 7.8 per cent respectively. It must be noted that there were few bacteremias, 14 and 16 per cent. Drs. Spitz, Bennett and I also found a low incidence of bacteremia throughout the pneumonia season of 1939-1940. These facts undoubtedly influenced the mortality rates. During the past year we have used sulfapyridine and sulfathiazole alone and in conjunction with serum and have obtained results comparable to those presented by Drs. Flippin, Schwartz and Reinhold. Serum alone was used in a group of cases treated during the period between December 1937 and May 1939. This series was composed of 320 patients of types I, II, V, VII, VIII and XIV pneumonia treated only with homologous refined and unconcentrated rabbit antipneumococcus serum. Rabbit antipneumococcus serum compares favorably with the chemotherapeutic agents in the treatment of these types of pneumonia. There were 126 cases of type I pneumonia and in 27.1 per cent of these bacteremia was present. The mortality rate in the cases of bacteremia was 20.6 per cent. The mortality rate was 2.2 per cent in the cases in which bacteremia was not present. There were 47 patients with type II pneumonia, 33.4 per cent of whom had bacteremia and of these 18.2 per cent died. There were no nonbacteremic deaths. In 44 cases of type V pneumonia there was a bacteremic incidence of 22.7 per cent. None of these patients died. The mortality rate of the nonbacteremic patients was 2.9 per cent. There were 46 patients with type VII pneumonia with 34.8 per cent bacteremia and of these 12.5 per cent died. None of the nonbacteremic patients died. With type VIII pneumonia there were 38 patients, 31.6 per cent of whom had bacteremia. There were no deaths. There were 19 patients with type XIV pneumonia. The bacteremic incidence was 15.8 per cent and the bacteremic mortality was 33.3 per cent. None of the nonbacteremic patients died. It is difficult to compare our results with those of Drs. Flippin, Schwartz and Reinhold, since they

included 21 patients treated with sulfapyridine and 16 patients treated with sulfathiazole for whom specific serum was used also because there had been an unsatisfactory response to the chemotherapeutic agents. There is one important comparable factor in the drug and serum treated groups—the bacteremic rates. Among the sulfapyridine treated patients the bacteremic rate was 14.2 per cent; among the sulfathiazole treated patients it was 16.2 per cent, whereas among our serum treated patients it was 27 per cent. The mortality rate of our serum treated patients, including 27 per cent with bacteremia, however, was only 4.7 per cent. This low figure undoubtedly demonstrates the efficacy of the serum. The patients in this series received serum, on an average, ninety-two hours after the onset of illness. It is significant too that the temperature of almost 65 per cent of the 303 patients who recovered by crisis fell to normal within twelve hours, while 80.6 per cent had a normal temperature within twenty-four hours and 95.4 per cent had a normal temperature at the end of forty-eight hours. These figures can be compared with those presented by the authors. In the sulfapyridine and sulfathiazole treated groups only 25 per cent and 10 per cent respectively had a normal temperature at the end of twenty-four hours. Of importance is the fact that in 79 per cent of our cases this initial projected dose was successful in producing a crisis. These time elements are of particular importance when one considers that in a critical case of pneumonia a few hours delay in supplying sufficient effective therapy will unfavorably influence the outcome.

DR. JOHN F. CASEY, Boston: The profession is indebted to Dr. Flippin and the other men who have done careful scientific work on the use of these drugs in pneumonia. I agree that sulfathiazole is much less toxic than sulfanilamide or sulfapyridine. When you are giving these drugs watch the urine carefully for gross blood. If it occurs give plenty of water and, as a rule, the blood will disappear promptly. The way to cut down the mortality of pneumonia in this country now is for the general practitioner to carry these drugs, either sulfapyridine or, I think, eventually it will be sulfathiazole, with him. If you have to wait long for typing of sputum, for roentgenograms or blood counts, you have lost valuable time. I think it is important that the drug should be given as soon as you see the patient, and in adequate dose. The first dose is important. If I give sulfathiazole I give 3 Gm. for an initial dose and keep it up with 2 Gm. every four hours. If sulfapyridine is used, I give 2 Gm. every four hours for four or five doses. As a rule in sixteen to eighteen hours with the sulfapyridine and a little longer time with the sulfathiazole one gets results.

DR. HARRISON F. FLIPPIN, Philadelphia: Whether pneumonia has been mild this winter it is difficult to say. Certainly we have not found it so at the Philadelphia General Hospital and, as pointed out, 18 per cent of our patients represent type III infections. At this time I see no apparent reason to compare the therapeutic effectiveness of serum and chemotherapy. All patients with pneumococcal pneumonia should be given sulfathiazole or sulfapyridine, unless contraindications exist, and serum is administered where indicated. In our experience serum is given, in addition to drug therapy, in about 10 per cent of cases. I would emphasize the importance of maintaining a urinary output of 1,000 cc. daily in order to facilitate the excretion of these compounds by the kidneys. Although our experience with the various chemotherapeutic agents for pneumonia is limited, it is our feeling at the present time that the drug of choice in the treatment of pneumococcal pneumonia will prove to be sulfathiazole.

Miliary Tuberculosis and Fibroid Phthisis.—Fulminating pulmonary tuberculosis, such as miliary tuberculosis, is rather infrequent among persons in better circumstances, while fibroid phthisis is more likely to occur among persons under better economic surroundings. Extremely acute manifestations of rheumatic infections are relatively infrequent among the better-to-do, while the more chronic type of fibrosing mitral stenosis is more likely to occur. In both tuberculosis and rheumatic fever these differences are conditioned by better treatment, ability to obtain more rest, less arduous occupation and other considerations.—Hedley, O. F.: *Pub. Health Rep.*, Oct. 11, 1940, p. 1858.

ARTERIAL HYPERTENSION

CORRELATION OF CLINICAL AND EXPERIMENTAL OBSERVATIONS

A. C. CORCORAN, M.D.

AND

IRVINE H. PAGE, M.D.

INDIANAPOLIS

Increased arterial pressure of known or suspected causation occurs in at least forty-seven syndromes, which, according to pathogenesis, are grouped as neurogenic, endocrine, cardiovascular and renal.¹ However, as a problem in clinical practice, hypertension is largely limited to those syndromes called essential and malignant hypertension. The genesis of these states, which had been regarded as renal since the time of Bright, has remained obscure since their separation from glomerulonephritis in the works of Allbutt, Janeway, Volhard, Keith and others.

The demonstration by Goldblatt² that lasting hypertension occurs after partial compression of one or both main renal arteries by a metal clamp revived interest in the relationship of the kidneys to increased arterial pressure. Experimental hypertension of similar nature was subsequently induced by one of us,³ who produced fibrocollagenous perinephritis by application of silk or cellophane to the kidneys. Compression of the renal parenchyma in the scar resulted in hypertension. The experimental disease which results from either of these procedures is in most respects similar to essential and malignant hypertension in man, and, as a result, new concepts of their pathogenesis were formed. Our purpose in this report is to review the application of these concepts to the clinical problem of high blood pressure.

HUMORAL MEDIATORS

Since it forms the basis of subsequent discussion, a chemical system which links the substances that appear to be mediators of renal hypertension must first be reviewed. Briefly, renin, a protein present in the cortex of normal kidneys, although not detectable by present methods in renal venous blood of normal dogs, is liberated in increased amounts into the renal vein by the kidneys of dogs made hypertensive by renal arterial compression or by perinephritis.⁴ Renin alone does not cause vasoconstriction when perfused with Ringer's solution through isolated blood vessels. However, in blood it combines, possibly enzymatically, with a substance present in normal plasma, provisionally termed renin activator.⁵ The interaction of renin and renin activator liberates a third substance, angiotonin.⁶ Angiotonin is a highly active vasoconstrictor distinguished from most substances which increase blood pressure in that it does not cause a decrease of cutaneous temperature during its pressor action. Given in doses which increase arterial pressure, angiotonin

causes vasoconstriction, which, in the kidney, predominates in the glomerular efferent arterioles.⁷ Significantly, it also increases the force of the heart beat.⁸

Normal dogs develop tolerance to successive doses of this substance. Tolerance occurs to only a small degree when both kidneys have been removed or seriously damaged.⁹ From this and other observations evidence has accumulated which indicates the presence in normal blood and normal kidneys of a substance which inhibits the action of angiotonin. Attempts to extract such an inhibitor or antipressor substance from the kidneys have been partially successful both in the hands of Grollman, Harrison and Williams¹⁰ and in ours.¹¹

CLINICAL PHYSIOLOGY

Those who have seen and felt the precordiums of patients suffering from hypertension have received the impression that the heart is laboring. The thrust and heave of the heart are obvious manifestations of increased force of its beat, just as elevation of diastolic pressure is evidence of peripheral resistance to the outflow of blood. The extent and effectiveness of cardiac augmentation in hypertension are shown in the fact that, in spite of peripheral vasoconstriction, there is no evidence of decreased peripheral blood flow. The feet and hands are warm, and there are no claudication, no cyanosis, no fainting and no renal failure until late in the course of the disease. Blood flow is maintained at efficient levels because the heart has increased its effort in propelling blood through the resistant arterial tree. Neither increased arterial pressure nor adequate peripheral blood flow can be maintained in the presence of vasoconstriction unless the heart increases the force of its beat.

The connection between peripheral vasoconstriction and cardiac augmentation is evident with a little reflection. Embryologically the heart is a specialized part of the vascular system. Therefore it is not surprising that the stimulus which increases peripheral tone should also augment cardiac effort. It is an important generalization that heart and arterial tree are not independent in hypertension; consequently, when, with the progress of the disease, increased cardiac effort may lead to premature failure, this event should be considered neither an incident nor an accident but an important phase in the natural evolution of hypertension.

Clinical observation, which has led us to a definition of the role of the heart in hypertension, also establishes the site of peripheral constriction. It is commonplace that patients suffering from this condition are not

usually pale, that the color of their nail beds is good and the temperature of the skin normal. In them, vasoconstriction is not the result of closure of capillaries and, in this respect, differs from the constriction which follows injections of epinephrine or solution of posterior pituitary. Examination of the one place where small arteries and arterioles are open to inspection, the ocular fundus, shows at once that constriction has occurred in these vessels. We may therefore conclude that increased arterial pressure in hypertension is the result of a stimulus which causes constriction of small arteries and arterioles and at the same time augments the force of the heart's beat. The reader will recall that angiotonin is capable of these effects.

As the hypertensive process continues, it results in hypertrophy of arteriolar and cardiac muscle. Arteriolar and cardiac cells increase until growth begins to exceed the limits of efficient diffusion of nutriment into them, so that regressive and degenerative changes occur. These cellular changes are reflected in cardiac failure, in cerebral and retinal lesions due to sclerosis, thrombosis or rupture and in disturbances of renal and digestive functions. With the passage of time, either as the result of cardiac failure or of arterial and arteriolar disease, blood flow through vital organs decreases until death supervenes.

Malignant hypertension, which may complicate the course of essential hypertension or which may be present from the onset of increased arterial pressure, is characterized by retinal hemorrhages and papilledema, with progressive renal, cardiac or cerebral failure leading to death usually within two to three years. Pathologically, it is manifested in widespread necrosis of the cells and obliteration of the lumens of arterioles. Clinically, the necrotizing arteriolitis and intense vasoconstriction are reflected in the retina by hemorrhages and exudates; in the heart, by ominous changes of sound and rhythm (e. g. gallop rhythm) and electrocardiographic record; in the kidney, by hematuria, proteinuria and renal failure; in the brain, by confusion, headaches and seizures. It is interesting to note in this connection that fractions have been obtained in the purification of renin by Winternitz¹² which, when injected, cause arteriolar necrosis and hemorrhages similar to those of malignant hypertension.

THE KIDNEYS IN HYPERTENSION

The usual tests of renal function may show no abnormality in the earlier phases of essential and malignant hypertension. Urea clearance, which measures the rate of removal of urea from blood by the kidneys, is frequently normal. Less commonly, the capacity of the kidneys to do work as measured by the power to concentrate urine is also unchanged. These observations would lead to the conclusion that the kidneys in early hypertension are entirely normal if other methods of examination did not disclose the presence of a characteristic renal abnormality.¹³ This functional disturbance may be demonstrated by the use of methods which measure separately the rate of flow of blood through the kidneys (calculated from plasma clearance of diodrast) and the rate of filtration of water from blood in the glomeruli (inulin clearance).

Observations have recently been reported (Corcoran, A. C.; Kohlstaedt, K. G., and Page, I. H.: *Proc. Soc. Exper. Biol. & Med.*, to be published) on the effect of intravenous injections of solutions of angiotonin in human beings. Single injections of from 0.5 to 1 cc. of the solution caused increased systolic and diastolic pressure over a period of about eight minutes. Slow infusion of angiotonin increased arterial pressure over longer periods, greatly decreased renal blood flow and increased filtration fraction, apparently as the result of intense efferent arteriolar constriction. Neither pallor nor subjective complaints were observed during the increase of arterial pressure.

Filtration of water and dissolved solids, such as urea and inulin, depends on the pressure exerted within the glomeruli on the blood plasma. Normally from 16 to 20 per cent of the water is filtered into the renal tubules. In hypertension more than 20, even 30 or 35 per cent, of the plasma water may be forced through the glomerular membrane.¹⁴ This increased filtration can occur only as the result of elevated intraglomerular pressure. Since it cannot arise from increased systemic arterial pressure alone,¹⁵ the increased intraglomerular pressure of hypertension might conceivably result from (a) opening arterioles proximal to the glomeruli (afferent arterioles) or (b) from constricting arterioles distal to the glomeruli (efferent arterioles). If the increased pressure were due to dilatation of afferent arterioles, the resistance to the flow of blood through the kidneys would be decreased, so that we would expect increased renal blood flows in hypertension. Actually, the rate of renal blood flow is decreased. The increase of intraglomerular pressure is therefore due to constriction of the efferent arterioles, which at once increases the filtration pressure and restricts the flow of blood through the kidneys. It will be recalled that this is one of the characteristic effects of angiotonin.

The maintenance of normal urea clearance in hypertension is due to this abnormality. Urea clearance is a measure of the rate at which urea is filtered from the blood into the renal tubules. With efferent arteriolar constriction less blood may pass through the glomeruli, but relatively more water and urea are filtered off. If, for example, renal blood flow in a patient suffering from hypertension has decreased 30 per cent, an increase of filtration pressure sufficient to squeeze 26 instead of 20 per cent of the plasma water and urea through the glomeruli would maintain urea clearance at a normal rate. Such a finding is not uncommon. The hypertensive patient is not therefore to be congratulated unreservedly on a normal urea clearance, since the normal finding may express intense efferent arteriolar constriction.

Renal vasoconstriction and ischemia in time result in degenerative and occlusive arteriolar changes which interfere with the normal nutrition of the renal tubules. As these die or lose their capacity to work, the kidneys are no longer able to concentrate urine by reabsorbing water from the glomerular filtrate. In its late phases this loss of renal tissue will be manifested in nocturia and polyuria. Long before the onset of these symptoms there will have occurred impairment of the maximum power of the kidneys to form urine of high specific gravity, so that the patient, when deprived of fluids for twenty-four hours, forms urine of specific gravity less than 1.028 (Addis concentration test) during the last twelve hours. The decrease of maximum concentrating power occurs in most cases months or years before urea clearance falls to abnormal values. It is the earliest clinical measure of impaired renal nutrition. Later, as arteriolar occlusion extends to wider areas, renal blood flow decreases until increased filtration pressure no longer maintains urea clearance within normal levels. The fall of urea clearance is therefore more ominous than a decrease in the maximum urinary specific gravity, and, in malignant hypertension, the progress of the disease may be gaged from the rate at which urea clearance falls.

NERVOUS SYSTEM

The worried, tense, complaining, fretful and resistant attitude of many patients suffering from essential hypertension is known to every physician. In many cases the onset of headaches is regularly associated with emotional stress. Nearly all show exaggerated responses of mood, mental content and blood pressure to the dissonances of daily life. In some the removal of obvious sources of conflict or direction toward readjustment of interests and better understanding of themselves and the world results in recession of symptoms and a decrease of arterial pressure. Many physicians are familiar with the fall of blood pressure and general improvement which may follow a trusting change to a "new doctor" as well as the rise of pressure and return of symptoms which will occur if the patient's full confidence has not been gained. In a few cases psychoanalysis has resulted in sustained improvement, and it is interesting to note that psychologically difficult phases of the analysis were sometimes associated with exacerbations of the symptoms.¹⁶ The important role of the mind in hypertension is therefore evident. It follows from this that such patients require the ungrudging time and emotional energy of a firm, consistent guide.

Somatic manifestations of mental origin other than increased arterial pressure may appear in hypertensive patients. Thus, a syndrome occurs, most commonly in young females, in which hypertension is associated with symptoms of cortical stimulation of the diencephalon.¹⁷ This state, the hypertensive diencephalic syndrome, is characterized by spontaneous or easily provoked blushing (over the face and neck), crying, laughter, salivation and tachycardia. These symptoms occur with little or no change of mood or mental content. The symptom complex is easily confused with hyperthyroidism and probably accounts for some of the apparent failures of thyroidectomy. The importance of this syndrome lies in the fact that the prognosis of such patients as to both life and freedom from organic disability is good.

Evidence of participation of the nervous system in hypertension may also be drawn from the effect of extensive operations on the sympathetic nervous system (anterior nerve root sections, total splanchnic resection, bilateral removal of thoracic and lumbar sympathetic chains). These operations, but especially the more recent types of sympathectomy, result in many cases in partial disappearance of hypertension and gratifying recession of symptoms and some prolongation of life.¹⁸

From the experimental side, it is interesting to observe that lasting hypertension may be produced by section of the inhibitory sinoaortic nerves¹⁹ or from the injection of kaolin into the cisterna magna²⁰ and

that complete sympathectomy with cardiac denervations lowers to normal the arterial pressure of dogs with such neurogenic hypertension.²¹ Equally interesting is the observation that extensive sympathectomy in dogs with renal hypertension has little immediate and no permanent effect on the level of arterial pressure.²² This failure of response in renal hypertension in dogs as compared with the response to sympathectomy in some human beings in whom hypertension seemed in part of renal origin may be attributed to the relatively lower level of psychogenic and neurogenic influence on the reactivity of the blood vessels in dogs.

THE ENDOCRINE SYSTEM

The relation of the endocrine system to the level of arterial pressure is known to the clinician from his knowledge of hypotension in Addison's disease and of hypertension in pituitary basophilism and certain adrenal carcinomas. This association of the pituitary and adrenal glands with arterial pressure is borne out experimentally in renal hypertension.

Removal of the hypophysis, the master gland, causes partial lowering toward normal of arterial pressure in experimental renal hypertension.²³ The same is true of bilateral adrenalectomy when adequate supportive doses of adrenal cortex extract and salt are given.²⁴ Removal of one adrenal and demedullation of the other does not alter the level of arterial pressure. Thyroidectomy, gonadectomy and pancreatectomy are similarly without effect.²⁵ The action of the pituitary gland seems to be exercised through its control of the adrenal cortex.

Clinically, neither hypophysectomy nor purposeful adrenalectomy has been practiced in hypertensive man. However, administration of desoxycorticosterone to patients suffering from the functional adrenalectomy of Addison's disease may so increase the reactivity of the vascular system that blood pressure may increase to hypertensive levels.²⁶ Thyroidectomy and gonadectomy are apparently without effect on hypertension in human beings.

Clinical and experimental observation therefore parallel and complement each other. It may be concluded that the adrenal cortex, although it may not itself participate in the mechanism which raises arterial pressure, serves at least to maintain the vascular tree in a reactive state to the stimulus which provokes hypertension. A similar generalization may apply to the role of the nervous system.

CORRELATION WITH THE HUMORAL PRESSOR SYSTEM

The components of the humoral pressor system were reviewed at the outset of this report. Their relation to the pathogenesis of hypertension may now be filled in.

Experimentally, renal hypertension due to constriction of the main renal arteries or to compression of the renal parenchyma in the scar of perinephritis occurs in "essential" and malignant phases. In the "essential phase" systolic and diastolic pressures are elevated, and cardiac and arteriolar hypertrophy and sclerosis develop with the passage of time. It is an important observation that sclerosis does not occur in the kidneys, which are protected from the increased arterial pressure by the clamp or rigid scar. Renal function as measured from the clearances of urea, creatinine, inulin, phenol red and diodrast may remain within normal limits.²⁷

Malignant hypertension in which arteriolar necrosis results in retinal hemorrhages, papilledema, exudates and detachment, cardiac irregularities, renal failure and gastrointestinal bleeding may supervene.²⁸

The renin content of renal venous blood is increased in both essential and malignant phases, and the blood contains an excess of a vasoconstrictor which, like angiotonin, is inhibited by normal blood and potentiated in the presence of blood from animals previously nephrectomized.²⁹ When renal extracts containing the angiotonin inhibitor are given to experimentally hypertensive animals a reduction of arterial pressure usually begins within twelve to twenty-four hours of the administration of an effective dose, and the reduction of pressure may persist for several days after treatment has been discontinued.³⁰ The reduction of arterial pressure is associated with relaxation of the glomerular efferent arterioles and a resultant increase of renal blood flow and decrease of filtration pressure.³¹

Observations which are in many respects similar have been made in human beings. The blood of patients suffering from essential and malignant hypertension contains an excess of angiotonin-like vasoconstricting substance.²⁹ The renin content of renal venous blood has been measured in several instances, and it is interesting that renin was present.⁴ Arterial pressure is reduced and, in malignant hypertension, life is prolonged by administration of renal extracts which contain the angiotonin inhibitor. The antipressor action of the renal extracts is associated with relaxation of the constricted glomerular efferent arterioles and a resultant restoration toward normal of renal hemodynamics.²⁸

Experimental and clinical observations therefore suggest an important participation of the renal humoral pressor system in hypertension.

SUMMARY

Angiotonin or renin plus activator when injected into animals produce those effects which have been shown to characterize arterial hypertension in man, namely cardiac augmentation, arteriolar constriction and constriction of the efferent arterioles of the kidneys. This suggests the possibility that angiotonin is involved in the pathogenesis of essential and malignant hypertension in man.

The endocrine system, notably the adrenal cortex and hypophysis, appear to participate indirectly in that their secretions maintain the blood vessels and heart in a state receptive to hypertensive stimuli. The nervous system may play a similar part, especially in some types of hypertension in man, in which the high state of nervous organization may even make it a prepotent factor.

The clinical picture and course of each case of hypertension is therefore probably a composite of the degree and kind of renal, endocrine and nervous participation.

CLINICAL SYMPTOMS ASSOCIATED WITH THE SO-CALLED NON- PATHOGENIC AMEBA

MAURICE M. ROTHMAN, M.D.

Instructor of Gastroenterology, Graduate School of Medicine, University of Pennsylvania; Chief of Gastro-Intestinal Clinic, Medical Service Number 2, Mount Sinai Hospital

AND

HARRY J. EPSTEIN, M.D.

Junior Adjunct in Gastroenterology, Medical Service Number 2, Mount Sinai Hospital
PHILADELPHIA

It is our purpose in this paper to present our clinical observations over a period of five years on 406 patients harboring one or more of the five forms of human intestinal ameba. These patients represent a cross section of the types of cases and complaints usually encountered in a gastrointestinal clinic. They were all given antiamebic treatment and the results are here recorded. This study is also intended to emphasize:

(a) the lack of uniformity in the observations made by various workers¹ in this field;

(b) the greater incidence of all types of intestinal ameba in man than is generally recognized;

(c) the responsibility of protozoa other than *Endamoeba histolytica* for the symptoms produced;

(d) the advisability of classifying all forms of ameba as potential pathogens, since they probably are capable of producing, to a moderate degree, many of the same symptoms produced by *E. histolytica*.

(e) that active pseudopodial amebas, in the absence of cysts, are in the average laboratories frequently mistaken for *E. histolytica*² and treated as such, thus detracting from the importance of the other four protozoa as symptom producers (pathogens).

Surveys have shown that protozoa are the most prevalent of all human parasites. It has been estimated that more than thirty million people³ in the United

States are infected with one or more of these organisms. Of these people from 2.5 to 10 per cent harbor *E. histolytica*, from 15 to 31 per cent *Endamoeba coli*, from 10 to 37.7 per cent *Endolimax nana*, from 2 to 3.5 per cent *Iodamoeba bütschlii* and from 2 to 4 per cent *Dientamoeba fragilis*.⁴ It has been generally accepted that only *E. histolytica* is pathogenic to human beings, while the other four forms of intestinal ameba are nonpathogenic. This opinion was no doubt fostered principally by the experimental work of Walker and Sellards,⁵ in Manila in 1913, who reported results of feeding experiments on 40 volunteers. One half of these subjects were fed cysts of *E. histolytica*, and of these 18 became parasitized and in 4 diarrhea developed. The other half were fed cysts of *E. coli*, and of these 17 became parasitized and in none did diarrhea develop. Musgrave⁶ seriously questioned the logic of the experiments and considered the results inconclusive.

Notwithstanding these experimental results in man and animals, which conclude that *E. coli* is not pathogenic, there have appeared in the literature records of clinical observations of symptoms caused by these organisms. In 1879 Grassi⁷ reported the finding of *E. coli* in patients suffering from diarrhea. In 1904 and again in 1926 Musgrave⁶ declared that the presence of ameba in the colon should be regarded as potentially dangerous from the clinical standpoint. In 1921 Kofoid⁸ and Swezy described a new species of ameba, which they called *Councilmanila laffeyi*, and stated that it was present in 10 per cent of all persons. They claimed that it may produce symptoms of colitis of similar character and of equal severity to that seen in any case of chronic amebiasis due to *E. histolytica* in the temperate zone. Furthermore, they were able to relieve patients harboring this organism with antiamebic therapy. In 1925 Hall and Reed⁹ described the symptoms produced by the *Councilmanila* type *E. coli*. From the results of the treatment they concluded that *E. coli* was potentially pathogenic.

In 1930 Lynch¹⁰ asserted that the pathogenicity of *Councilmanila laffeyi* was still under suspicion. Stabler proved conclusively in 1938 that *Councilmanila laffeyi* and *E. coli* were identical organisms. To us these observations were of great significance, not because of the identification of the *Councilmanila laffeyi* as one of the forms of *E. coli*, but because they suggested the fact that *E. coli* could produce symptoms. In 1926 Brown¹¹ described a number of cases of dysentery in which he found either *E. coli* or *Endolimax nana*. At that time he presented sound theoretical reasons for their causal relationship. Among other writers claiming that these two organisms were pathogenic to man

may be mentioned Orticoni and Gazzola¹² in 1922. Rankin, Bergen and Buie¹³ concluded from their clinical study in 1934 that *E. coli* and *Endolimax nana* should be considered pathogenic when found in patients with gastrointestinal symptoms. Another ameba reported as capable of producing symptoms was *Dientamoeba fragilis*. Reports by Robertson,¹⁴ Thomson and Robertson,¹⁵ Hakansson¹⁶ and Wenrich¹⁷ also suggest its pathogenicity.

RECOGNITION OF AMEBA

For complete details on the various forms of amebas, the reader is referred to any accepted textbook on clinical parasitology. Craig and others¹⁸ have frequently drawn attention to the fact that at the present time there are but few laboratory technicians trained in this difficult phase of parasitology. It is the opinion of most workers that the identification of the cyst yields more reliable results than identification of the trophozoite. Many laboratories employ only the wet saline smear and stain with iodine solution as the simplest and most practical method.¹⁹ There are, however, many workers who rely entirely on the iron hematoxylin stain. It is sometimes difficult to differentiate the fresh active pseudopodial trophozoite of

E. coli or *Endolimax nana* from *E. histolytica* as regards motility, ingestion of red blood cells,²⁰ ectoplasm, nucleus and the like. Many believe it a safe rule to regard as *E. histolytica*²¹ any ameba in the feces of man which contains red blood cells. However, since it is admitted that *E. coli*²² and *Endolimax nana*²³ may also ingest red blood cells, it is unfortunately impossible to determine the number of patients who, under such mistaken diagnoses, have been treated for *E. histolytica*. Furthermore the precystic amebas

of *E. histolytica* and *E. coli* are virtually indistinguishable from one another, even to the most expert observers.²⁴ When only trophozoites of ameba are found, some suggest waiting for the development of cysts²⁵ before making a diagnosis. This does not apply to *Dientamoeba fragilis*, for which no cyst has been described.

PATHOLOGY

Faust states that in the majority of cases of heavily infected persons in regions in which the incidence of *E. histolytica* infection is high the organism is not a tissue parasite²⁶ but a commensal and that *E. histolytica* did not always produce gross lesions in man or in all species of monkeys. On the other hand, Craig²⁵ is

TABLE 2.—Control Study: Ameba-Free Patients Treated with Carbarsone: Three Negative Stools

Total Number	Improved	Not Improved

under the impression that all carriers of *E. histolytica* show some evidence of tissue invasion. He reviewed reports of autopsies on groups of men and monkeys in which colonic symptoms were not found but there were amebas in the feces. He found ulcerative lesions in the cecum of all of them and concluded that there is no such thing as a healthy carrier of *E. histolytica*. The autopsies on the monkeys were done after an acute experiment. The autopsies on human subjects were performed in the tropical zone. However, one cannot accurately compare the autopsies performed in the tropics with those performed in the temperate zone. David Meranze, pathologist at the Mount Sinai Hospital, has performed more than one thousand five hundred autopsies in the past ten years. He was rarely able to demonstrate gross lesions of the cecum which could be called amebic ulcers. Nevertheless, if one were to accept Craig's analysis, at least 5 per cent, or 75 cases, should have been observed.

Craig²⁵ found the strongest positive results with his complement fixation test in symptomless carriers. In contrast, Sapero²⁷ reported that almost 50 per cent of *E. histolytica* carriers had symptoms directly or indirectly attributable to the organism. Since the complement fixation test is evidence of a systemic reaction and since others²⁸ have also shown that other forms of ameba are capable of producing symptoms mildly

similar to those produced by *E. histolytica*, is one not justified in assuming that they may also produce a systemic reaction? If this is so, then one may hope some day to have a complement fixation test for them. Almost all our patients were examined with a sigmoidoscope and 109 of them showed a spastic sigmoid with a dry thickened hyperemic mucosa (table 1). In spite of the fact that a dry, spastic, irritable colon

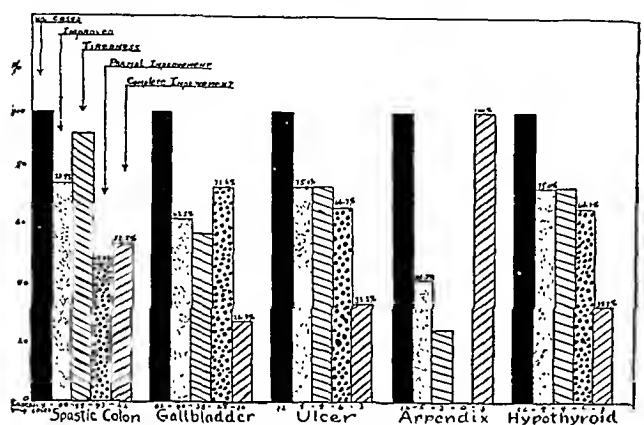

Chart 1.—Tiredness associated with selective diseases.

might be attributed to any one of a great number of causes, the marked improvement demonstrated sigmoidoscopically in so many of these cases following antiamebic therapy suggested that pathologically and clinically the protozoa may have been responsible for the inflammatory reaction.

METHOD OF STUDIES

Since we were planning an evaluation of the clinical improvement resulting from specific treatment, it became obvious that no claim of complete relief of symptoms would be possible in cases of complicated chronic sinusitis, cholecystitis, peptic ulcer, ulcerative colitis and the like. It was therefore necessary to devise some simple mathematical formula for "subtraction of symptoms relieved" from the total number of symptoms present. Symptoms persisting after adequate therapy were then interpreted as due to complicating conditions. This formula will be referred to as the "rule of subtraction."

Our results with antiamebic therapy in these cases were so striking that it was deemed of importance to determine the tonic versus the specific effect of the arsenic used. It was also of interest to ascertain what part suggestion played in the results obtained. Almost all the patients were given 3¾ grains (0.25 Gm.) of carbarsone (para-carbamido-phenyl-arsonic acid; arsenic content from 28.1 to 28.8 per cent) twice daily for ten days. A small group of patients with ameba in their stools were given solution of potassium arsenite in the usual therapeutic doses for a period of ten days, and the effects were noted. While under treatment they also were placed on the same diet as that prescribed for our active cases. Disappearance of symptoms or of amebas was not recorded in any case. For practical purposes we set a limit of three negative stools as evidence of the absence of amebas. However, like other workers,²⁹ we have seen cases in which as many as 10 or more specimens were examined before protozoa

were found. There are numerous reasons to account for this difficulty, but space does not permit their discussion.

A course of carbarsone was administered under the same conditions to another group of patients not infected with amebas. Of 28 patients in this group, 24 showed no relief of symptoms and 4 were improved (table 2). Whereas Paulson³⁰ is somewhat inclined to attribute the improvement in his cases to the tonic effect of the arsenic, we feel equally justified in assuming that the improvement was due to the presence of amebas which we failed to find. The effects of the specific therapy were usually manifest in from three to five days, or before the first course of treatment was completed. Admitting the absence of deliberate psychic influence, the tonic, nonspecific effect of arsenic would not usually manifest itself in so short a time. Furthermore, it does not seem possible that almost 50 per cent of these results should be due to suggestion.

SYMPTOMATOLOGY

Amebiasis is defined by Musgrave⁶ as any pathologic condition caused wholly or in part by protozoa of the genus *Endamoeba*. Amebiasis per se can be responsible for many symptoms associated directly or indirectly with the colon. Many of our patients had coexisting diseases (table 3) the symptoms of which frequently distracted attention from the symptoms due to the amebic infection. In order to evaluate properly which of the several symptoms were due to one or the other disease, the problem was approached in the fairest possible manner. For this purpose it was considered important first to eradicate the amebas in all cases of multiple infections. A careful record was kept of the symptoms which disappeared during and after the treatment. Those symptoms which persisted after the treatment was given were interpreted as being due to the accompanying infection. Paulson³⁰ believes that the only way that the protozoal symptom relationship can be evaluated is after disappearance of all symptoms. It is generally known that diseases of the colon may mimic some of the diseases of the upper part of the abdomen, such as ulcer or diseases of the gallbladder or kidneys.

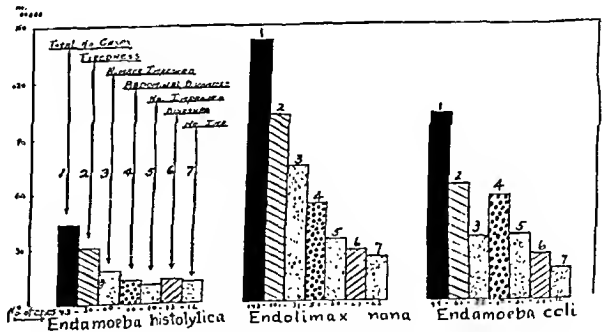

Chart 2.—Outstanding symptoms associated with *Endamoeba histolytica*, *Endolimax nana* and *Endamoeba coli*.

The patients here considered were never really seriously ill but suffered symptoms of only mild or moderate character. As a rule they are unable to date the onset of the illness. The symptoms, although annoying, seem vague and unimportant, so that frequently no medical attention is sought. There may be slight indigestion, a fleeting abdominal cramp or gaseous

29. DeYoung, Willard: Sources of Error in the Laboratory Diagnosis of Amebiasis, *J. Lab. & Clin. Med.* 21: 1249 (Aug.) 1936. Meyer and Johnstone.¹³ Magath.¹⁵

30. Paulson, Moses and Andrews, Justin: The Role of Symptoms and Signs in Amebiasis, *Ann. Int. Med.* 12: 64 (July) 1939.

distress most commonly located below the navel. The symptoms may be confined to the lower right quadrant and be mistaken for appendicitis. The patient may feel tired on arising as from inadequate rest in spite of from eight to ten hours of sound sleep and may seem unable to get started until about 11 a. m. and by late afternoon is ready to lie down again. It is an effort for him to move but, once started, he gets along well enough. He is easily exhausted by the slightest exertion, has lost his "pep," does not feel like standing erect and does so only with an effort.

The stools may become altered, at times mushy or even watery, but more frequently there is constipation. Bowel elimination does not seem to relieve the abdominal discomfort entirely. The patient may suddenly experience a sense of well-being for several days or weeks and go on to complete recovery. This may be the result of a temporary or permanent immunity or because most of the protozoa have been washed out. He may remain well until they multiply again in sufficient numbers to produce symptoms. The presence of these organisms in the intestine may by their local effect or, if we may presume, their "toxic" effect, aggravate the coexisting diseases. They may also retard or prevent a normal response to the treatment of these diseases.

Hall and Reed⁹ suggest that patients with vague, minor or apparently functional symptoms who have been diagnosed as neurasthenic or neurotic should have their stools examined for protozoa. In a large number of such cases, in which examination revealed nothing but *E. coli*, good results were obtained from antiamebic therapy.

For a clear picture of etiology and symptom relationship, it was necessary to group apart those patients with one form of ameba from those with two or more forms (table 4). Of 406 patients with all forms of ameba 258, or 63.3 per cent, complained of feeling tired and 184, or 45 per cent, felt weak. Thus 70 per cent of all patients harboring *Endolimax nana* alone and 61.6 per cent of those harboring *E. coli* alone felt tired, as compared to 69.9 per cent of the patients with *E. histolytica*. Two hundred and seven patients complained of constipation, although this was not necessarily due to the presence of the amebas. A number of the patients were cured of their constipation which had developed with the onset of symptoms. Diarrhea or mushy stools were observed in 68 cases. In 23 of these *Endolimax nana* was the only form of ameba found, in 15 cases *E. coli* and in 13 cases *E. histolytica*, while in the remainder of the group two or more forms of ameba were present. One hundred and sixty-three patients complained of some abdominal discomfort. This is suggested as being due to the presence of the amebas by the simultaneous disappearance of the discomfort and of the amebas. The most common site of abdominal distress was below the navel, most frequently in the lower right quadrant. Twelve patients with these symptoms were given a tentative diagnosis of appendicitis. Those harboring two or more forms of ameba were interesting in that a greater number of them had symptoms possibly due to symbiosis. Thus 80 per cent of these complained of feeling tired and the like. In 12 cases, hypothyroidism was diagnosed because of marked asthenia, hypotension, increased cholesterol and low basal metabolic rate. Their response to thyroid medication was not commensurate, but in 9 cases removal of the protozoa produced from good to excellent results.

RESULTS

It was interesting to observe the results of treatment of patients with many symptoms and to estimate the numbers caused by amebas by using the "rule of subtraction." These results were based on observation and follow-up from one month to six years of 406 cases of all forms of intestinal ameba; 179 of these, or 44.1 per cent, improved following eradication of the protozoa. The most prevalent was *Endolimax nana*, which was encountered 184 times. It was found alone in 143 cases and in 41 cases together with other forms of ameba. Eighty, or 55.9 per cent, of cases with a

TABLE 5.—Results of Antiamebic Therapy

Total Cases	Males	Per Cent	Females	Per Cent	Total Improved	Per Cent
406	160	39.4	246	60.6	179	44.1

single type of ameba showed some improvement, while in 20 per cent of this group the results were excellent. Second in importance from a numerical standpoint was *E. coli*. It was found in 172 cases, in 99 instances without other forms of ameba and in 73 with one or more of the other forms. Forty-five patients, or 45.3 per cent, showed some improvement.

Jodamoeba bütschlii was observed in 8 cases. It was never found alone, so that we were unable to evaluate its clinical importance. Furthermore, those patients in whom it was found did not show any more distinguishing symptoms than did the other three forms of ameba under consideration.

Some of our patients were found to have a recurrence of the ameba within six months to two years. It was difficult to determine whether it was due to inade-

quate treatment or to reinfection. We are inclined to believe that they were reinfected because this is apt to occur unless contacts are taken seriously and are thoroughly treated.

To summarize the treatment briefly: Patients were placed on a high protein, low carbohydrate, high vitamin diet.³¹ Most patients were given one or two courses of carbarsone. In several instances a course of vioform-Ciba and emetine hydrochloride was also given. It is remarkable to note the difficulty in finding cysts and trophozoites of ameba in these cases of mild involvement after the third day of treatment with carbarsone, and by the fifth day the protozoa had disappeared entirely. This was not usually observed when we started the treatment with emetine hydrochloride. Craig prefers to reserve the use of emetine hydrochloride for special cases and advises against its routine use.²⁵

REPORT OF CASES

CASE 1.—A white woman aged 62, the wife of a physician, suffered for four months with diarrhea and severe pains in the lower part of the abdomen. She was admitted to a hospital, where she was treated for diverticulitis. She was discharged as unimproved, after which cancerophobia with dysuria and frequency of urine developed. Six weeks later she was admitted to another hospital, where she was treated unsuccessfully for two weeks. When first seen in the office, sigmoidoscopic examination revealed a spastic sigmoid with an edematous and hyperemic mucosa. A smear from the sigmoid revealed many actively motile trophozoites and cysts of *E. coli*. Treatment was started immediately, and within five days she began to show signs of improvement. Within ten days she was clinically better, passing formed stools, and the acute hyperemia in the sigmoid had almost disappeared. She has remained well for the past six months.

CASE 2.—A white man aged 39 suffered for three weeks from violent cramps and ten to fifteen watery bowel movements daily. He did not respond to the usual diarrhea therapy given him elsewhere. On first examination, trophozoites of *E. coli* were recovered through the sigmoidoscope. The mucous membrane was hyperemic and edematous. Three days after antiamebic therapy was started, the diarrhea and cramps ceased. He was completely well in ten days, and his sigmoid appeared normal within three weeks.

CASE 3.—A white girl aged 16 years was seen in consultation with a surgeon because of acute pain in the lower right quadrant of the abdomen and fever. There was pain but no tenderness or muscle guarding in the lower right quadrant. Her father was being treated for infection with *E. coli*. As a contact with the same protozoa in the feces she did not receive antiamebic therapy because she was menstruating at the time. Treatment is usually withheld during the menses, because while a patient is on carbarsone therapy the urine should be watched for albumin, red blood cells and casts. The surgeon wanted to operate, but as the leukocyte count was normal, antiamebic therapy was permitted. This produced a rapid recovery. There has been no recurrence of the symptoms for the past three years.

CASE 4.—A white woman aged 35 for three and one-half months after an attack of grip continued to have an elevated temperature ranging between 99.1 and 100.5 F. She had occasional chills and was very tired and weak. All studies including cultures of blood and excretions, and roentgen examinations were negative except for *Dientamoeba fragilis* in the stool. She had many consultants who, when informed that *Dientamoeba fragilis* was present, unanimously stated that it could not produce symptoms. Every possible therapy was given including sulfanilamide, azosulfamide, quinine and blood transfusions, all without any change in her condition. The third day after antiamebic therapy was started her temperature dropped to normal. She has had no recurrence for the past twelve months.

CASE 5.—A white woman aged 35 had a cyst adenoma removed from the thyroid gland in January 1939. Her pre-operative basal metabolic rate was -7 and the postoperative -20 per cent. Before the operation she had complained of extreme tiredness and exhaustion. Thyroid and vitamins were given without any influence on the patient except to elevate the basal metabolic rate to -5 per cent. She summered at the seashore but failed to regain her strength. In October the study of her stools showed the presence of cysts of *Endolimax nana* with as many as from 20 to 30 per high power field. Five days after treatment was started the patient felt a sudden change for the better. On the tenth day she was in excellent condition. Two weeks later she did not feel as peppy and, although no protozoa were found in the stools, a second course of carbarsone was given. She responded in the usual time and has been feeling excellent since.

CASE 6.—A physician aged 40 suffered for ten weeks with discomfort in the lower right quadrant and shooting cramps across the upper part of the abdomen, followed by loose, explosive bowel movements. These attacks occurred about once a week, and except for being unusually tired he was well during the intervals. Stool specimens contained 1 or 2 cysts and trophozoites of *Endolimax nana*. Antiamebic therapy brought about complete relief of symptoms. He states that he feels as though he could now do twice as much work as before treatment.

COMMENT

Amebiasis represents a very important problem from the point of view of public health. About 35 per cent of the population in and about large cities are infected with one or more protozoa.²² This compares favorably with from 50 to 75 per cent²³ of the population in some small towns of the South. In the office and laboratories, where the time element is not a factor, the percentage increases with experience, the time spent and the number of specimens examined.¹⁹ It is estimated that about fifteen million or more persons have symptoms attributable to the parasitic effect of these forms of ameba. At this rate 44.1 per cent, or about thirteen million persons, may perhaps be benefited either in part or completely by their eradication. It has been suggested that this is not practical,²² yet the attempts to eradicate smallpox, typhoid, yellow fever, malaria and other diseases were no small undertaking. It has been shown that these amebas are capable of producing many symptoms mimicking functional and organic conditions. Antiamebic therapy was followed in 44.1 per cent of the cases by some expression of relief. If the patient would not express himself favorably then the presence of the ameba was assumed to be commensal.

The internist is often consulted because the patient complains of being weak or tired. Many diseases must be ruled out, but in the absence of symptoms suggesting some colonic disturbance how often does he think of protozoa? Protozoan infection is the most common and universal disease of man; it is the least understood of all human infections. It appears simple to the one who constantly sees and works with it. He recognizes the specific ameba and treats the condition. Clinically the patient may be cured of the infection and the symptoms which accompanied it. This has been demonstrated time and again by several observers,²³ but unfortunately they represent only a small minority group.

There still are many of the common diseases, such as colds or measles, for which Koch's postulate has never been fulfilled. We believe that the same may be true of the experiments with *E. coli*. We

31. Faust, E. C.: Amebiasis in Dogs, *Am. J. Trop. Med.* 12: 37 (Jan.) 1932.

32. Lynch: Protozoan Parasitism of the Alimentary Tract, p. 26.

are inclined to believe that *E. coli*, *Endolimax nana* and *Dientamoeba fragilis* may produce symptoms as debilitating as a cold except that the symptoms are usually of a chronic nature. Nevertheless, not because of the absence of clinical conditions but based on experimental evidence only, these protozoa have been considered nonpathogenic. There are a great many circumstances which may influence an experiment, such as bacterial symbiosis, environment, virulence of the parasite and the susceptibility of the host. Musgrave⁶ gave many reasons for believing that the results of the feeding experiments to prove the "harmlessness" of *E. coli* were inconclusive. He states that diarrhea is not a necessary symptom and that the absence of clinical symptoms and ulcerations in the rectum is not necessarily evidence of the absence of ulceration higher up. The fact that amebas are present in the stools of patients without producing symptoms is not acceptable evidence of harmlessness, because patients have been observed for many years with *E. histolytica* in their stools without the production of symptoms. Nevertheless clinical colitis as severe as that observed with typical *E. histolytica* is occasionally seen when prolonged search reveals nothing but *E. coli*.²³ We have also seen and successfully treated with antiamebic therapy patients suffering with violent cramps and diarrhea in whom nothing but *E. coli* was found. We have likewise made similar observations on persons, groups and families harboring only *Endolimax nana*. Some clinicians²⁴ referring to these claims state that it represents merely a failure to find *E. histolytica*. We admit such a possibility but to not more than 10 per cent; otherwise, all protozoal surveys which have shown the existence of *E. histolytica* in our part of the country of from 5 to 15 per cent are wrong and should be closer to 50 per cent.

Although at the present time there exists a reluctance to accept the pathogenicity of *Endamoeba coli*, *Endolimax nana* and *Dientamoeba fragilis*, we hope that this report will stimulate further clinical and experimental investigations.

CONCLUSIONS

1. Stool specimens from 406 patients located in and about Philadelphia harbored one or more of the five forms of intestinal amebas. The most prevalent was *Endolimax nana*; *E. coli* was second.

2. These organisms, including *Dientamoeba fragilis*, had a causal relationship to their symptoms to the extent of 44.1 per cent.

3. The most common symptoms were constitutional; i. e., extreme tiredness and weakness. Of local nature were abdominal discomfort and diarrhea.

4. When a coexisting disease is active the results to be expected may be only partial; i. e., only those symptoms for which the ameba is responsible will disappear.

5. The response to carbarsone therapy is usually within three to five days. When no improvement is noted by the tenth day one may be fairly certain that the symptoms were not due to the presence of the ameba.

6. From a clinical point of view, all forms of ameba appear to have a pathogenic role. Furthermore, since they may represent a serious public health menace and problem, it is suggested that they should be accepted and treated as such until clinical evidence to the contrary can be proved.

1727 Spruce Street.

ABSTRACT OF DISCUSSION

DR. ASHER WINKELSTEIN, New York: Drs. Rothman and Epstein state that amebas other than *Endamoeba histolytica* may be pathogenic. It might be stated that this is debatable. There is as yet no conclusive evidence, clinical or pathologic, about it. They also say that the protozoal infection is common (35 per cent of the population). It must be admitted that it requires experts to find and differentiate the amebas, and more trained workers are certainly needed in this field. One fourth of their cases showed a spastic sigmoid with a dry hyperemic mucosa. I have had a large experience with sigmoidoscopy and do not consider this a pathologic finding. Their control group, 28 patients with symptoms without amebas, were treated with carbarsone without relief. This seems to answer the objection that arsenic itself may induce the tonic effect; however, the symptom complex described by them is so vague and broad that the small control group selected may have little significance. The symptom complex of asthenia and vague abdominal symptoms with constipation or diarrhea, while indefinite, is one of the most common symptom complexes seen in general practice. In my experience it is most often a neurosis. The finding of various amebas may have no more significance in this group than in any other group of the population even without symptoms. Their patients were treated with diet, vitamins and carbarsone. There was improvement in 44 per cent of the *Endolimax nana* and *Endamoeba coli* groups. It is surprising, if indeed there is a causal relationship between these amebas and the symptoms, that only half of the patients were helped. The authors conclude that some 35 per cent of the population is infected with these amebas and that this constitutes an important public health problem. Before accepting this conclusion, however, I feel it must first be proved that these amebas are pathogenic and, if so, that carbarsone cures these patients. Nevertheless, I wish to commend strongly the authors for bringing this important subject to the fore. It deserves a careful check-up study.

DR. HORACE W. SOPER, St. Louis: Early in my work I formulated a rule that every patient, no matter what his complaint, should receive a careful feces analysis and proctosigmoidoscopy. By employing this method I have been able to diagnose many cases of catarrhal colitis that might have been otherwise overlooked. By catarrhal colitis I mean that the feces will contain an excess of mucus, some of which will contain pus cells. In the majority of cases *Amoeba coli* or some of the flagellates are present. The proctoscopic picture usually shows a congestion of the mucous membrane of the rectum and pelvic colon. I reported a case of acute jejunitis about two years ago in the *American Journal of Digestive Diseases and Nutrition* that was definitely produced by *Trichomonas intestinalis*; the roentgenogram, the dilatation stopping abruptly at the ligament of Treitz, made the diagnosis of carcinoma. The abdomen was opened and an active jejunitis was found which responded to acetarsone therapy. I use acetarsone in preference to carbarsone because I consider it more toxic to the parasites and rarely toxic to the patient.

DR. PALMER DYSART, Phoenix, Ariz.: My experience is in accord with that of Drs. Rothman and Epstein, but, with Dr. Soper, I would add *Giardia*, *Chilomastix* and the *Trichomonas* flagellates to the pathogens which they presented. This is a remarkable survey of a condition that is difficult to follow. A group of us in Arizona, when presented with a case of vague gastrointestinal distress, of which the outstanding symptoms are fatigue, abdominal pain, gas and nausea, with or without relation to meals, and constipation more often than diarrhea, but also perhaps joint pains, neuritis and headaches, including migraine, in which one or more of these parasites are found, feel, like Drs. Rothman and Epstein, that we may have discovered the cause of their complaints. Then, as a proof satisfactory to us that these parasites are pathogenic, when we have cleared the intestinal tract of these organisms we expect the majority of these patients to be relieved of symptoms, the exact statistics for which I do not have at hand. I admit that we may find these parasites in some without apparent disease. These may be carriers. Authority has stated that these organisms are not pathogenic. It will require, therefore, much proof to controvert this belief.

²⁴ Brown, P.: Personal communication to the authors.

DR MOSES PAULSON, Baltimore: If the deductions of Drs. Rothman and Epstein are correct, we have just passed an important milestone in clinical protozoology. Unfortunately, they have failed to prove their contentions experimentally, statistically and clinically. Experimentally there are no available data acceptable to recognize protozoologists establishing amebas other than *Endamoeba histolytica* to be of pathologic import. Nor has any experimental evidence been offered here indicating otherwise. Statistically and clinically the following must be considered: Less than 50 per cent of the patients studied have been partially—not completely—relieved of symptoms on eradication of nonpathogenic amebas. At the same time a high vitamin, high protein, low carbohydrate diet (reduced residue-reduced stimulating routine) was given. Since many patients suffered from constipation it is fair to assume, although there is no specific mention of this by the authors, that they were treated also for this complaint. These two measures could account for much of the reported amelioration. The addition of adequate psychotherapy in cases in which there are similar complaints without structural change to account for them has in my experience resulted in a higher percentage of symptomatic relief either in the presence or in the absence of nonpathogenic protozoa. This is not to say that nonpathogenic protozoa should not be eradicated. A clinical entity or syndrome cannot be claimed unless the set of symptoms is completely eliminated with the eradication of the presumed etiologic agent in the vast majority of cases. The greater number of the authors' cases that failed to respond and many others that did so partially are to me the controls disproving the claim. The work that Andrews and I did about three years ago at the Johns Hopkins Hospital appears pertinent. The role of symptoms and signs in those with *Endamoeba histolytica* was studied. The number of cases was not large but the data appeared statistically valid, since no exceptions were encountered. Eliminating those having *Endamoeba histolytica* with diarrhea or dysentery, those manifesting *Endamoeba histolytica* with other digestive complaints for which no structural change could be held accountable were given carbarsone. For several weeks to a month or two many were completely relieved. Then all returned with their original complaints despite our inability to find amebas. When given antispasmodics, sedatives and hypnotics, all were completely relieved again. When these were discontinued the complaints recurred but still no amebas were to be found. Coincidentally with reinstitution of this therapy, complete relief was again obtained.

DR. ANTHONY J. BASSLER, New York: In the city of New York about 7 per cent of people have parasites and about 4 per cent have *Endamoeba histolytica*. I think it is much to be desired to remain on the side of the old teaching of parasitology of the past, to be conservative with regard to these cases unless the symptoms are characteristic of amebiasis as we understand it. I feel this way: We do get flagellate diarrheas and we, of course, have amebiasis, and we do have many problems, and when one comes to parasites found in a case, one is inclined to attach a significance to it, and, as Dr. Paulson has said, there are many things that can happen in the abdomen (I counted them up not long ago and they numbered two hundred and forty-two conditions that can happen in an abdomen). Most of these are functional and they are characterized by the protean symptoms expressed. Thus we should be careful not to give significance to something that really is not causative.

DR. MAURICE M. ROTHMAN, Philadelphia: In answer to Dr. Winkelstein's question as to why only one half of our patients were relieved, we believe that those 44.1 per cent relieved represent the number whose symptoms were attributable to the presence of the ameba. As to the proof of pathogenicity of these organisms, we are unable at the present time to offer direct experimental evidence. However, it is unfortunate that there also exist many other diseases for which we recognize a pathologic entity but for which Koch's postulates have never been completely satisfied. The common cold and many other diseases caused by a virus are such examples. Dr. Soper believes that flagellates are pathogenic. This is of interest because we, as well as other clinicians, are of a like opinion. Nevertheless many of these same men unhesitatingly

deny a similar role of pathogenicity for amebas other than *Endamoeba histolytica*. One of the reasons is based on the fact that they are not capable of invading tissue. Yet it is recognized that flagellates are not tissue invaders. Our observations are in accord with the experience of Dr. Palmer Dypart, who found constipation to be more common than diarrhea. In regard to Dr. Paulson's statement concerning the lack of experimental evidence, we prefer to regard the past experiments as a failure to reproduce the clinical picture rather than proof of the evidence of the absence of pathogenicity. Furthermore, there have never appeared in the literature reports of the failure to obtain some relief following specific treatment of patients with symptoms harboring the so-called nonpathogenic amebas. In this study we have found that diet, vitamins and the relief of constipation did not alleviate specific symptoms without the removal of the ameba. We believed it advantageous first to dispose of the protozoa. By so doing one can determine the exact symptoms due to the presence of the organisms. This is especially important in the presence of coexisting diseases. This has a direct bearing on Dr. Paulson's recent report on the treatment with carbarsone of 26 cases of *Endamoeba histolytica*. It is not unusual to obtain symptomatic relief with nonspecific therapy, but if those symptoms are due to the presence of the ameba they will recur. Most of our results were lasting, while those which were not were due either to inadequate treatment or to reinfection.

Clinical Notes, Suggestions and New Instruments

EXFOLIATIVE DERMATITIS AND DEATH DUE TO PHENOBARBITAL

DANIEL L. SEXTON, M.D.; GEORGE M. PIKE, M.D., AND
ARTHUR NIELSON, M.D., St. Louis

The toxic effects of phenobarbital, for the most part, are limited to a cutaneous eruption which subsides soon after the withdrawal of the drug. In an occasional case a severe constitutional reaction occurs in which exfoliative dermatitis is one of the manifestations.

The first case of exfoliative dermatitis reported due to phenobarbital was that by Hamilton, Geiger and Roth¹ in 1926. Although there was an exfoliation of all epidermal layers, recovery occurred after a prolonged illness.

Eleven cases of severe cutaneous eruption were reviewed by Poole,² another by Haubrich³ and two by Lancaster,⁴ in one of which there were marked urticarial wheals and the patient died five days after the rash appeared. This patient was being treated for a fracture and had received 85 grains (5.5 Gm.) of phenobarbital.

Autopsy reports on the subject are few. Bronchopneumonia has been reported in a majority of the cases, but otherwise the conditions found are inconstant. Brunsing⁵ recorded the death of a patient in whom severe systemic symptoms and large bullae developed. At autopsy there were no remarkable conditions seen.

At postmortem examination of a patient with nephritis who had received a preparation of theobromine and phenobarbital, which included 24 grains (1.5 Gm.) of phenobarbital over a period of eighteen days, Millard⁶ found renal damage and bronchopneumonia.

From the medical (Drs. Sexton and Pike) and the dermatologic (Dr. Nielson) service, Unit 11, St. Louis City Hospital.

6. Millard, R. J.: Three Cases of "Luminal" Poisoning, *M. J. Australia* 2:518 (Oct. 14) 1933.

Scarlett and MacNab⁷ record the history of a patient who received 19½ grains (1.26 Gm.) of phenobarbital over thirteen days. Twelve days after the drug was started the patient's temperature rose, and there occurred a macular rash which eventually developed into large, bullae, intense conjunctivitis and stomatitis. This patient died six days after the rash appeared. Toward the end the total nonprotein nitrogen was elevated. Autopsy showed evidence of encephalitis, for which the patient had originally been admitted and from which he had recovered clinically, and cloudy swelling of the kidneys and liver.

Switzer and Laymon⁸ reported two cases of severe cutaneous reactions following phenobarbital with one death after 1½ grains (0.1 Gm.) daily for three weeks. This patient had exfoliative dermatitis and at postmortem examination only bronchopneumonia and fatty changes in the liver, which may have been due to the gallstones present, were found.

Wile and Benson⁹ reported two cases of exfoliative dermatitis following phenobarbital with fatal outcome. One, a dentist aged 48 who had received a total of 44 grains (2.85 Gm.) of phenobarbital over a period of nineteen days, had universal exfoliative dermatitis. At postmortem examination were found dilatation of the right side of the heart, bronchopneumonia, acute bilateral purulent bronchitis and subendocardial fatty degeneration. The other patient, a man aged 45, had received a total of 42 grains (2.7 Gm.) of phenobarbital over fourteen days before a maculopapular rash developed. The rash became exfoliative and death occurred thirteen days after its first appearance. Changes found at autopsy included a bullous, ulcerative and exfoliative dermatitis, bilateral lobar pneumonia, acute diphtheritic laryngitis and esophagitis, acute passive congestion and degeneration of all parenchymatous organs.

Because of the few autopsy records available on this subject, the following report is made:

REPORT OF CASE

P. M., a white man aged 39, admitted to the St. Louis City Hospital Dec. 1, 1939, complained of epigastric pain and vomiting of three months' duration. He had had indigestion with belching and epigastric distress after meals for many years in varying degrees of severity, but this became so marked in the two weeks prior to entry that practically no food was retained. He stated that he had not taken any medication or drugs before entrance.

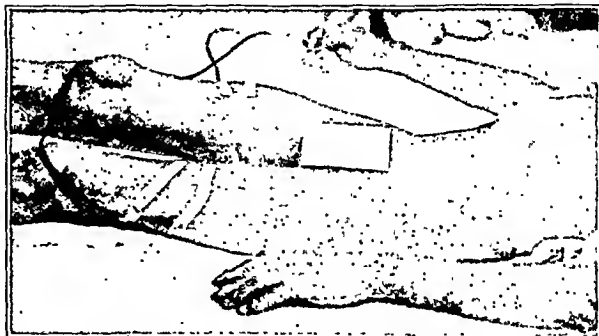

The patient was poorly nourished, almost emaciated, but was comfortable at the time of examination. Except for epigastric tenderness on deep palpation, examination revealed nothing abnormal. The oral temperature was 97.8 F., pulse rate 78, respiratory rate 18, blood pressure 123 systolic, 75 diastolic.

Urinalysis on admission showed no sugar or albumin, and microscopic examination of the sediment was negative. The hemoglobin content measured 12.5 Gm. (Sahl), red blood cells numbered 4,020,000 and white blood cells totaled 7,800. A differential count showed 2 per cent juveniles, 6 per cent stab cells, 54 per cent segmented forms, 33 per cent lymphocytes, 4 per cent monocytes and 1 per cent eosinophils. Analysis of gastric contents yielded normal amounts of free hydrochloric acid. The Kahn precipitation test gave negative results. Blood sugar was 55 mg. per hundred cubic centimeters (normal, from 70 to 95 mg.); nonprotein nitrogen was 14 mg. (normal, from 11 to 26 mg.). Stool examination showed no gross or occult blood.

The clinical diagnosis was peptic ulcer, and accordingly a first day Sippy diet was ordered. Three grains (0.2 Gm.) of phenobarbital was given on the night of admission. Because of vomiting, subcutaneous medication consisting of 1 grain (0.065 Gm.) of soluble phenobarbital three times daily and ¼ grain (0.4 mg.) of atropine sulfate three times daily was started the next day. The patient did very well on this regimen. On the eighth hospital day soluble phenobarbital and atropine were omitted, and 1½ grains of phenobarbital orally three times a day was ordered.

Improvement continued until the twelfth hospital day, when the patient complained of a feeling of general malaise and the previously normal temperature rose to 103 F. At this time he had no specific complaints and no eruption. On the following morning the temperature was 104 F. and the patient complained of sore throat and dysphagia. He was acutely ill with injected conjunctivas and excessive lacrimation. The skin was covered with a generalized eruption, consisting of discrete erythematous macular lesions. In the mouth were numerous vesicular lesions, some of which had ruptured and released a thin, milky fluid. There were moist rales throughout both lungs. The white cells numbered 16,600 with a shift of the left in the Schilling differential count. There was no eosinophilia. The urine showed no material changes from the examination on admission.

Up to this point the patient had received 21 grains (1.36 Gm.) of soluble phenobarbital subcutaneously and 21 grains of phenobarbital by mouth over a period of thirteen days. The drug was immediately discontinued and parenteral fluids were started. Dr. Joseph Grindon Sr. of the dermatology service saw the patient in consultation and made a diagnosis of dermatitis medicamentosa due to phenobarbital. Within twenty-four hours the cutaneous lesions progressed so rapidly that in many places they became confluent, involving large areas of skin, which soon began to exfoliate; the exfoliation is shown in the accompanying illustration. The patient became semicomatose, with a temperature ranging between 104 and 105 F., until his death on the morning of the sixteenth hospital day, three days after the appearance of the eruption.

Eruption as it appeared on second day after onset. Note areas of denudation over abdomen.

Autopsy was performed two hours after death. Over the skin of the entire body were numerous brownish red to pink areas in which the superficial layers of the skin were lost. To the edges of some of these lesions were attached large sheets of exfoliating grayish skin. These lesions were present on the ears, face, neck, chest, back, abdomen, scrotum, arms, legs and feet. The trunk showed the most generalized distribution. Some of these areas of exfoliation measured as much as 15 cm. in diameter. Many were confluent.

The right pleural cavity contained 300 cc. of straw colored fluid. The middle and lower lobes of the right lung and the lower lobe of the left lung were moderately firm but not typical of pneumonic consolidation. A hemorrhagic purulent exudate was seen in the secondary bronchi of both lower lobes. Microscopically the lung showed many alveoli filled with polymorphonuclear leukocytes, and in one section several small necrotic areas were seen. The epithelium of the esophagus was absent and in its place was a layer of fibrinopurulent exudate. The liver and kidneys were normal. No evidence of ulceration was found in the stomach or duodenum.

COMMENT

The potential danger of phenobarbital should be kept in mind. It would seem advisable to administer the drug first in small doses, increasing the dosage gradually until the patient's tolerance is established. Withdrawal of the drug at the first appearance of the rash is the safest procedure. Even then a severe constitutional reaction may occur, but for the most part a fatal outcome will be averted. The tolerance of phenobarbital depends on individual susceptibility.

Special Article

GLANDULAR PHYSIOLOGY AND THERAPY

MENSTRUATION

GEORGE W. BARTELMEZ, PH.D.
CHICAGO

This special article is published under the auspices of the Council on Pharmacy and Chemistry. It is one of a series which will be published in book form as the second edition of "Glandular Physiology and Therapy." The opinions expressed in this article are those of the author and do not necessarily represent the views of the Council.—ED.

In the human species, menstruation is the only overt manifestation of rhythm in the female reproductive system. In other primates there may be additional and even more obvious indications of cyclic changes. Corner^{1d} and Edgar Allen^{1c} have recently summarized the evidence that the rhythm is maintained by a delicate balance of endocrines. We are not dealing with "an all or none" phenomenon but with a balanced system of forces which changes as a whole when any one factor changes. The oscillations of the system may have a high amplitude or they may become almost imperceptible. The system is accordingly variable in its manifestations. This is generally conceded; the difference of opinion is largely a matter of the range of variability that is to be regarded as normal. Many clinicians are unwilling to regard a cycle as normal unless its primary purpose is achieved; i. e., unless a fertilizable egg is produced. The fundamental controlling mechanism is nevertheless the same whether the optimal conditions which result in ovulation are achieved or not. In other words, there may be bleedings at regular intervals which are clinically indistinguishable from menstruation although the ovary has not responded to the extent of producing a ripe egg.

Physiologic extravasations of blood are a unique feature of the mammalian uterus. Before a scientific treatment of abnormal "functional" bleedings is possible it will be necessary to analyze the mechanisms which control normal bleedings. The analysis requires controls that can be applied only in experiments with animals. The problem seems at present to be centering about the utero-ovarian vascular system, and some consideration of the vascular changes is definitely indicated in experiments with estrogen, progesterone and similar substances.^{1c}

In the human species and in certain monkeys three normal types of endometrial bleedings may be seen:^{2b}

1. Menstrual bleeding. This recurs at intervals of three to five weeks and is associated with rapid involution and some necrosis of the endometrium.

2. Implantation bleeding (placental sign of Long and Evans). This occurs soon after implantation of the ovum, in many mammals. In women and macaque monkeys it appears about four weeks after the last period,^{2a,c} and when it involves an external show of blood it may be indistinguishable clinically from menstruation. In such cases the onset of labor is a month earlier than expected from the history.

3. Preovulatory bleeding associated with hyperemia. This is the familiar estrous bleeding of the dog and cow; in primates it is the rather uncommon "intermenstrual" bleeding (mittelschmerz). It has been seen in the macaque at about the time of ovulation and after large doses of estrogen.^{1c}

The second and third types have received far less attention than they deserve.

The liberal definition of menstruation given here is justified by the finding that the ovaries and the uterus may present a very different appearance during successive periods in the same individual^{1c} and at the same stage in different individuals. In the macaque there have now been observed a large series of transitions from the maxima of the breeding season to the minima of summer. There may be extreme hyperplasia and hypertrophy of the uterus associated with an active corpus luteum in one cycle; occasionally it is impossible to tell from the endometrium whether or not ovulation has occurred. There are anovulatory cycles during which the endometrium grows more than in certain ovulatory cycles.^{1c} In such cases it is necessary to have serial sections of both ovaries to prove the absence of recent corpora lutea. In other words, ovulatory and anovulatory menstruation are not distinct types; cycles with much ovarian activity grade off imperceptibly into those with little. The "staircase phenomena" of Hartman^{2c} gave us the first clear evidence of this.

At present, anovulatory cycles appear to be rare in women whose periods are "regular."³ This may be due in part to the difficulty of demonstrating them. Usually it is necessary to have both ovaries removed early in a menstrual period which appeared as expected. Such cases are rare. Inspection of ovaries at operation and of fragments from endometrial biopsy specimens often lead to error, for the conditions in ovary and uterus may vary within wide limits, with transitions from ovulatory to anovulatory cycles, as the study of the macaque has abundantly shown.^{2d} There are few who can diagnose an active corpus luteum histologically. The incidence of anovulatory cycles will not be known until physicians have a sure sign of ovulation which can be readily applied to large groups of women for twelve or more consecutive cycles.

Hitherto knowledge of the sequence of events in the menstrual cycle has come from series of specimens arranged in an order that seemed logical to the investigator. Human ovaries have only occasionally been available, and it has been possible to exclude almost any given case as abnormal if the critic so desired. A large number of macaque uteri have now been studied, and one can say with assurance that the cyclic changes are fundamentally the same as in man.⁴ One can therefore accept the recent observations of Markcc^{1c} as applicable to human conditions with but little modification. He has launched a new attack on the cycle by observing living endometrium transplanted to the

anterior chamber of the eye in macaques. He could thus observe the same mucosa with a microscope day by day or minute by minute for many cycles in normal unanesthetized animals, and his experience has been extensive enough (432 menstrual cycles) so that he can speak with authority as to the essential features of the cycle. It is significant that the onset and duration of menstruation in these bits of endometrium coincide with the same events in the animal's uterus with its intact musculature. The observations agree with conditions observed in histologic sections, substantiating and extending them, but they do vastly more than this. They give one direct visual evidence of the actual sequence of events and the first satisfactory quantitative data on the same endometrium during a cycle and in different cycles. They exclude the nervous system as a significant factor in the control of the cycle. They furnish the basis for an analysis which includes all kinds of normal cycles. Markee calls it the "growth" rather than the "menstrual cycle." It may be subdivided as follows:

1. Postmenstrual phase of relative inactivity, which may vary in length from nothing to many days or even weeks.

2. Primary growth phase, which may or may not be associated with a growing follicle. The end of this phase is usually marked by a brief halt or even a regression in growth. The cause of this remains to be investigated.

3. Secondary growth phase, which reaches a maximum in the presence of an active corpus luteum. The endometrium may double in thickness, partly as a result of increasing edema.

4. Phase of involution. This is associated with a reduction in blood flow to the mucosa, and at the end there may be superficial congestion, leukocytosis and infiltration. The edema fluid is resorbed, and the involution may reach 60 per cent. Sooner or later there is persistent blanching of the surface due to constriction of the arteries which supply the surface.

5. Phase of bleeding. The constricted arteries open up, often one by one; almost at once there is extravasation, followed by bleeding from the surface and then by desquamation of the superficial zone.

6. Repair phase. This involves reestablishment of active circulation, rejuvenescence of the endometrium and restoration of the surface epithelium.

The vascular system of the endometrium plays a major role in this cycle. The peculiar coiled arteries are one of the most distinctive features of the primate endometrium. They pass with few or no branches in myometrium or basal mucosa to supply the superficial capillary bed⁵ and are "end arteries."⁶ At the beginning of the first growth period they are coiled in the mucosa basally. Capillaries pass out from them to the superficial reorganizing zone, which is rapidly increasing in thickness. The arterial channels gradually differentiate in this capillary bed and slowly approach the surface. Later the arteries grow more rapidly than the surrounding tissue, so that they become coiled throughout their length. Under the influence of the active corpus luteum they eventually differentiate as far as the surface epithelium.

The basal region of the endometrium has an independent supply of blood derived from small arteries and from anastomoses with the capillary bed of the myometrium. There is no sharp line of demarcation between this zone and that supplied by the coiled arteries. The drainage from the mucosa is by venules, which are predominantly radial, but with numerous anastomoses, which may enlarge into sinuses. Certain venules pass, without anastomoses, from the superficial to the deep veins of the endometrium. Lymphatics have been described, but their presence in the mucosa has not yet been proved.

Markee's^{1b,c} observations on transplants show that there may be much variability in a given endometrium even in successive ovulatory cycles. His descriptions provide the basis for the following résumé of a typical cycle.

During the first three weeks the coiled arteries alternately dilate and constrict, so that as one looks at the surface it slowly "blushes" and then "blanches," a cycle occupying one to one minute and a half. After the second growth phase is well under way the vascular rhythm is occasionally disturbed, and in general the color of the transplant becomes paler. Presently the blood almost stops flowing through the dilated superficial vessels. Leukocytes begin to migrate into the stroma; the transplant is turning blue and manifestly shrinking. There is a loss of water.⁷ With this involution, the tortuous arteries show buckling. These events herald the onset of menstruation. In the course of the next day one coiled artery after another clamps down, and for many seconds at a time not a single blood corpuscle moves in the superficial zone, although basally the blood is flowing freely. After several hours an artery here and there opens up, and almost at once blood pours out into the tissue from opened capillaries or arterioles. In the course of a few minutes a sub-epithelial hematoma develops, it soon ruptures, and dark blood slowly streams out over the surface. This blood does not clot. Necrosis sets in at the surface, and the ends of the coiled arteries are sealed by dead cells. Then fissures appear at the edges of blood-soaked areas; as they extend down into the tissue, small fragments are slowly loosened from the surface. An artery that has bled is not likely to bleed again during this flow, but if the animal is frightened or annoyed, the necrotic end may break and spout blood for minutes at a time. This blood promptly clots. Such conditions probably obtain in various metrorrhagias.⁸

At intervals during the next two days or so other arteries begin to bleed, and so the process is repeated, each time in a different region. By the third or fourth day the surface has become denuded and ragged; coiled arteries and glands project out from it, and veins are open. Slowly a little regurgitated blood oozes from an open vein for a period of many minutes. The wound surface looks clean, and most cells seem normal. Presently cells begin to migrate out in all directions from torn glands, and in two hours the surface epithelium is practically restored. During all the period of bleeding the circulation of blood has continued basally; now it is accelerated. Then the coiled arteries begin to develop capillary sprouts, which anastomose,

and blood flows through them. The rejuvenation of the superficial zone is now under way, and a new growth cycle has begun.

THE MECHANISM OF MENSTRUATION⁹

It is not yet possible to enumerate all the hormonal factors concerned in the control of the menstrual cycle. The interactions of anterior hypophysis and ovary are essential^{10,11} but other endocrines may normally be involved. So far as the mechanism which brings about bleeding is concerned it would appear from what has been said that the question can be narrowed down to the factors which control the coiled arteries of the endometrium.

The hormone withdrawal hypotheses^{9a} are fundamentally similar to the corpus luteum failure hypothesis of R. Meyer. That is, they attribute the menstrual changes to the elimination of a hormone or hormonal complex. It is now possible to say that ovarian hormone withdrawal initiates the characteristic premenstrual and menstrual behavior of the coiled arteries.^{1c}

Various observations indicate that it is not the elimination of a specific hormone but an abrupt reduction in hormonal level which produces this type of bleeding. These data may be summarized as follows:

1. Hisaw^{9f} found that a reduction of 50 per cent in the amount of estrogen administered to a spayed macaque results in menstrual bleeding. This has been abundantly confirmed and elaborated.¹⁰ Markee^{1c} has clearly demonstrated the importance of an abrupt change.

2. The thresholds in these reactions are vague and variable although it has been shown that in a spayed animal a definite minimal amount of estrogen is necessary to maintain the endometrium in a condition that will permit withdrawal bleeding.¹¹

3. In keeping with this variability is the fact that various insults to the ovary such as unilateral ovariectomy or even resection may produce menstrual bleeding. Similarly a profound systemic disturbance such as transection of the spinal cord initiates it.¹² As the level of the transection plays a part, it may be that the nerve supply of the ovary is involved in the reaction.

4. Bleeding during the course of treatment with estrogen may perhaps involve periodic hormone reduction through changes in renal thresholds.¹³

5. The reaction is not specific for any one hormone; the effects of estrogen, progesterone and androgen withdrawal are similar.¹⁴

The objection has been raised that the estrogen titer in the circulating blood may be high premenstrually and during menstruation¹⁵ and the premenstrual fall in estrogen excretion does not necessarily militate against this. It is true that quantitative determinations

in the blood hormones are fraught with many uncertainties, and some authors discard the findings on this basis; but it is always possible that in these cases there was a premenstrual fall from a still higher level.

Other factors besides ovarian hormones are concerned in the production of menstrual bleeding.

Markee^{1c} showed that the effect of "estrogen deprivation" is essentially local. After spaying an animal which had transplants in both eyes, he administered estrogen, which brought about the typical vascular rhythm and endometrial growth. Then he inserted a crystal of estradiol into one eye and stopped the subcutaneous injections of estrogen. The transplants in the other eye began to shrink and in due time menstrual bleeding occurred there and in the uterus. But in the eye that had the crystal, growth continued, and no menstrual changes were to be seen. After the end of the experimental menstruation the injections of estrogen were resumed, and growth was seen in all transplants. When the crystal was removed, menstruation was induced only in the treated eye, while the estrogen level in the circulating blood was sufficient to maintain growth in the transplants of the other eye.

All this may mean that the bleeding mechanism involves something more than reduction in ovarian products and raises the question of other factors.

Markee^{1c} has presented evidence that as soon as regression has set in, the menstrual process is controlled within the endometrium itself. His hypothesis is that continued regression produces progressive buckling of the coiled arteries even in cycles with feeble growth. This retards the flow of blood superficially to such an extent that the mucosa is injured. As a result the tissue produces a vasoconstrictor to which the sphincters of the coiled arteries⁶ are highly susceptible. They clamp down, and the resulting stasis brings on menstruation.

It may be that the reduction in hormonal levels activates a specific bleeding mechanism. The hypophysis as the source of such a factor seems to be ruled out.¹¹ Markee^{1c} reported greater irregularity in the blush and blanch rhythm during the second growth period, and this supports the idea²⁰ that the same specific factor responsible for the rhythmic blanching also produces the protracted premenstrual blanching. In such a situation regression would be initiated when a definite threshold was reached. So far the hunt for a specific vasoconstrictor has failed. Brewer¹⁷ presented evidence for a general vascular spasm premenstrually and suggested a substance resembling epinephrine as the agent. He attributed the premenstrual and menstrual changes to the gradual increase of such a vasoconstrictor in the blood.¹⁸ Such a hypothesis assumes that in pregnancy the activated corpus luteum antagonizes the vasoconstrictor to such an extent that extravasation is confined to the region already damaged by the invading ovum.

Why should there be a periodic weakening of the superficial endometrium and an outpouring of blood? The most satisfactory explanation is that the process is an adaptation to provide nourishment and a foothold for the fertilized ovum during the period when the placenta is being established.¹⁹

9. The mechanism of menstruation is discussed at length by (a) Allen, Edgar, Hisaw, F. L., and Gardner, W. V., in Allen, Edgar, Danforth, C. H., and Doisy, E. Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

GENERAL ELECTRIC LM-4 SUNLAMP
ACCEPTABLE

Manufacturer: General Electric Company, Appliance and Merchandise Department, 1285 Boston Avenue, Bridgeport, Conn.

The General Electric LM-4 Sunlamp generates ultraviolet radiation within the limits of the standards set by the Council for devices using the term "sunlamp." These standards require that the energy of wavelengths shorter than and including 2,800 angstroms shall not exceed 1 per cent of the total energy of wavelengths between 2,804 and 3,132 angstroms. These wavelengths fall in the spectral region of low erythematogenic action and render the sunlamp suitable for unsupervised use by the layman.

The ultraviolet source is mounted in a reflector which is supported by an adjustable stand. This stand consists of a base where the "slow-break" switch is located and a tubular column holding a bracket which allows for a 30 inch height adjustment of the reflector. This reflector may be tilted at any angle. All the wires are concealed, and there is an 8 foot cord with a rubber plug. The maximum height of the unit is 60 inches.

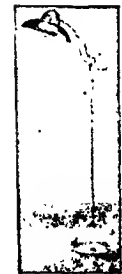

The source of ultraviolet energy, the type S-4 bulb, consists basically of a quartz mercury arc about 1½ inches long, enclosed in a special glass bulb which transmits ultraviolet wavelengths of 2,894, 2,967, 3,024 and 3,132 angstroms (and longer wavelengths) but which cuts off most of the wavelengths shorter than about 2,800 angstroms. The lamp produces the characteristic blue green light of the mercury line spectrum. The total power required is 120 watts, the line voltage 110-120; the lamp operates only on alternating current.

Relative Spectral Intensities

Wavelength (Angstroms)	Relative Energy (Average of 3 Lamps)
3,132	7.96
3,024	2.59
2,967	1.15
2,894	0.28
2,804	0.09
Total	12.07

In information submitted by the firm it is stated that five minutes exposure is required for a minimum perceptible erythema at 30 inches, or sixteen minutes at 54 inches.

To light the lamp the electrodes must be cool. When the lamp has been operating and turned off, up to two minutes is required before it will resume operation. The firm states that under average home use the life of the S-4 bulb is enough for more than a year's service.

General Electric LM-4 Sunlamp.

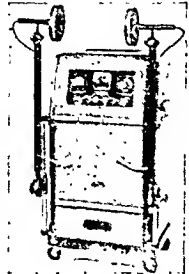

The radiation at 2,804 angstroms (and shorter if measurable) is about 0.75 per cent of the total of all wavelengths, including 3,132 and shorter. Mounted in an aluminum reflector the radiation at 2,894 angstroms and shorter, relative to the total, would be still lower; hence these lamps comply with the Council's requirements for acceptability of a sunlamp for spectral quality of ultraviolet radiation.

The Council voted to accept the General Electric LM-4 Sunlamp for inclusion on its list of accepted devices.

FISCHERTHERM MODEL 106-C-4
ACCEPTABLE

Manufacturer: The Fischer Corporation, 673-713 Ivy Street, Glendale, Calif.

The Fischerttherm 106-C-4 is designed for use in medical and minor surgical diathermy. Standard equipment includes pad, cuff, induction cable, surgical accessories and foot switch. Air-spaced electrodes are also available. The apparatus is housed in a wood cabinet 42 inches high, 22 inches wide and 16 inches deep. The weight is approximately 140 pounds.

Fischerttherm Model 106-C-4.

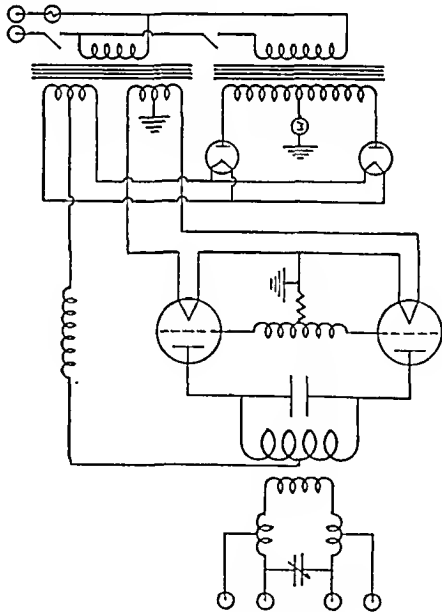

The apparatus provides a wavelength of 6 meters and utilizes two 354-C oscillating tubes and two rectifying tubes. It operates at 60 cycles, 115 volts.

In all the following tests, applications were given for twenty minutes and at an intensity corresponding to the patient's skin tolerance for heat. In applying the inductive cable, approximately 1½ inches of bath toweling was wrapped around the thigh and was held in place by approximately four turns of the inductive cable.

Results of Tests of Heating Tissue Submitted by the Firm

Technic	Deep Muscle, Degrees, F.		Oral, Degrees, F.	
	Initial	Final	Initial	Final
Pad	98.6	101.9	98.6	98.9
Cuff	98.9	104.8	98.7	99.2
Cable	98.6	104.0	98.5	99.1
Air-spaced disk	95.3	103.3	98.7	99.3

The Council's clinical investigation of the apparatus confirmed the firm's tissue heating tests.

Schematic diagram of circuit.

In order to determine the power output and the final transformer temperature, tests were conducted in a laboratory acceptable to the Council. The results of these tests are as follows:

Final transformer temperature (by resistance method)... 70.1 C.
(within the limits of safely prescribed by the Council)
Power output in watts..... 550 watts

The load was two 200 watt tungsten filament bulbs connected in parallel.

The Council on Physical Therapy voted to accept the Fischerttherm 106-C-4 for inclusion on its list of accepted devices.

THE MEDICAL STUDENTS MUST BE DEFERRED

At a joint conference which included the Committee on Medical Preparedness of the American Medical Association, the Subcommittee on Medical Education of the Health and Medical Committee of the Coordinator for Health and Welfare, and the Council on Medical Education and Hospitals of the American Medical Association, which was held in the headquarters of the American Medical Association in Chicago on February 15, it was determined, after extended discussion, to send the following telegram at once to Mr. Clarence A. Dykstra, Director of the Selective Service System, in Washington, D. C.:

1. Since the five year preparedness program of the government will require about three thousand five hundred medical graduates annually to enter the service of the Army, Navy and Public Health Service for a year's training, the education of physicians must be continued at the present level and without interruption.

2. This is so vital to military and general welfare that we urge the Director of Selective Service to make clear to draft and appeal boards that it is in the interest of the country to provide deferment of military service for students in good standing in approved medical schools who may be called for duty under the Selective Service Act until they shall have obtained the degree of doctor of medicine. The Committee on Medical Preparedness of the American Medical Association offers its facilities for the verification of the credentials and such other information as may be needed in connection with the application of any medical student for deferment.

3. In order to provide a continuing supply of qualified medical students for the medical schools of this country, we urge also that students who have been accepted for admission to approved medical schools in a period not to exceed twelve months preceding enrolment be granted deferment of military training in order that they may complete the requirement for admission to medical schools.

4. Suggestions that the number of medical students be increased can have no relationship whatever to the situation now confronting us because such an increase in the number of students admitted to medical schools during the current year could not in any way affect the number of doctors available for either military or civilian service before 1946. Such an increase of medical classes would surely tend to lower the quality of instruction and in the end cause a deterioration of medical service.

Evidence was presented at this meeting to indicate that the needs of the Army Medical Department for

each of the five year training periods set up under the Selective Service Law will be for eight thousand medical officers from civilian life each year. This in itself will place a tremendous demand on our medical resources.

About five thousand two hundred young men graduate each year from our approved medical colleges, and every one of them must have at least one year of internship. Once the internship is completed, at least three thousand five hundred of these graduates will be needed to enter the services of the Army, Navy and Public Health Service for a year's training. Indeed, it is reasonable to believe that some serious adjustments will have to be made by hospitals during the next two years because of this requirement. Many of the institutions which now provide a one and one-half or two year general internship will have to be satisfied with one year of service.

Several suggestions have been made to meet the need that exists. Thus some have suggested that the number of medical students for the freshman year be increased at once by 10 per cent in all of our approved medical schools. As is pointed out in the statement sent to Mr. Dykstra, this would not provide a single competent medical man before 1946. Moreover, the suggestion fails to take into account several important facts: first, that our medical schools now have about all the students that they can carry with the available faculty, facilities and equipment; second, practically every boy who is really competent to undertake the type of medical education required in an approved medical school now gains admission. The fact that some eight hundred who enter medical school fail to complete the course is an indication of the difficulties raised by the modern medical curriculum. Third, the faculties themselves are being placed in the pool of medical men available for positions as medical officers with troops and for the staffs and chiefs of service in the new Army hospitals, which will within the next year or two be increased by fifty thousand additional beds.

Almost preposterous is the strange suggestion emanating from some leaders in Washington that only third and fourth year medical students and interns be deferred. When it is realized that there is a constant and definitely anticipated loss of men from the medical schools from the day of first enrolment to the day of graduation, it can be recognized that any depletion of available medical students from the moment when they are accepted for entrance into medical school until they have finally completed their internship will be hazardous in times like these.

Several plans have been suggested for obviating the fact that the Selective Service Law does not provide for blanket deferment of any particular group. First, there is the possibility of amendment of the law. The medical profession does not ask this. Recognizing that blanket deferment of medical students would raise at

once the question of deferment of men who are studying medicine in schools conducted by medical cults and in schools of inferior grade, the medical profession is content with the concept that deferment may be secured if the Director of the Selective Service will make clear to draft and appeal boards that it is in the interest of the country to provide deferment of military service for medical students in good standing in approved medical schools. No one is asking exemption for these boys. All that is being asked is deferment until they shall have obtained the degree of doctor of medicine, when the vast majority of them may be depended on to take at once a year of medical military training and to be thereafter available in the organized medical reserve corps. The law does provide that persons in essential occupations for the maintenance of the public health and security may be deferred. Any policy which permits a single qualified student in an approved medical school to be taken out of that training and put into other military service is indication of a lack of foresight and of a failure to appreciate the actual needs of the nation in this emergency.

INDUCED THIAMINE DEFICIENCY IN MAN

Most of the experimental work on the role of the various food factors in nutrition has been necessarily carried out on animals. Accurate descriptions of the symptoms which result from uncomplicated vitamin deficiencies in experimental animals are available, while comparable information bearing on human beings is often lacking or is incomplete. Although the knowledge gained from animal experimentation has contributed immeasurably to our understanding of the role assumed by various vitamins in human nutrition, investigations of this type alone cannot yield all the desired information. Recently experimental studies have been made in which human beings have served as subjects. Although such investigations are difficult, they are amply justified in view of the great practical value of the results.

Many investigators have studied the experimental production of a deficiency of thiamine in man. Jolliffe and his associates,¹ for instance, maintained several subjects for a number of days on diets that were partially deficient in thiamine and were probably adequate in all other dietary essentials. The report on this study embodied a description of the disturbances encountered in the experimental subjects and contained useful information on the relationship between urinary excretion and intake of thiamine. Much additional information relative to the symptoms of thiamine deficiency in human subjects has been afforded by the extensive investiga-

tions of Williams and his associates.² The most recent report by these investigators is particularly worthy of attention because it not only furnishes more accurate information on the results of uncomplicated vitamin B₁ deficiency in man but also raises questions concerning the etiology of some of the common symptoms of beriberi and the requirement of this food factor.

In the latest experiments of Williams and his co-workers a number of persons were given a diet deficient in thiamine for a period of almost three months. The degree of debility induced by the withdrawal of thiamine from the diets of these persons was impressive; fatigue, lassitude and loss of interest in food developed early and increased progressively as the period of deficiency was extended. The time of development of severe symptoms was not the same for all and seemed to be related to physical activity, the more active subjects developing symptoms earlier. Depressed mental states, generalized weakness, dizziness, backache, soreness of muscles, dyspnea, insomnia, anorexia, nausea, vomiting, loss of weight, slight roughness of the skin and atony of muscle were encountered. Faint heart sounds, lowered blood pressure and bradycardia when at rest, and tachycardia and sinus arrhythmia on exertion were likewise observed. Changes in the size of the heart were not found in any case, nor was edema observed. The concentration of plasma proteins remained within normal limits in all cases, as did the values for calcium and phosphorus in the serum. Neither anemia nor cheilosis was present, but capacity for muscular work fell progressively. Also of interest was the development of electrocardiographic abnormalities, which consisted in the diminution of the amplitude of all complexes and particularly of the T waves of the chest leads.

These observations on the effects of uncomplicated thiamine deficiency in man are of unusual interest and importance. While edema, cardiac dilatation and peripheral pain are often encountered in beriberi, these symptoms were entirely lacking in the disease induced by restricting the dietary intake of thiamine. In view of their observations, Williams and his associates have been led to question whether a deficiency in thiamine alone is responsible for the classic features of beriberi. The investigators point out that the early stage of the disease induced by restricting the intake of thiamine closely resembles neurasthenia, while the later stage is similar to anorexia nervosa. This conclusion, of course, does not imply that all the patients with conditions diagnosed as neurasthenia can be shown to be suffering from thiamine deficiency. Indeed, it is possible that only a small percentage of such conditions is of nutritional origin, although it is likewise possible that the number is large. On the basis of their experi-

1. Jolliffe, Norman; Goodhart, Robert; Gennis, Joseph, and Cline, J. K.: The Experimental Production of Vitamin B₁ Deficiency in Normal Subjects: The Dependence of the Urinary Excretion of Thiamine on the Dietary Intake of Vitamin B₁, *Am. J. M. Sc.* 195: 198 (Aug.) 1939.

2. Williams, R. D.; Mason, H. L., and Smith, B. F.: Induced Vitamin B₁ Deficiency in Human Subjects, *Proc. Staff Meet., Mayo Clin.* 14: 787 (Dec. 13) 1939. Williams, R. D.; Mason, H. L.; Wilder, R. M., and Smith B. F.: Observations on Induced Thiamine (Vitamin B₁) Deficiency in Man, *Arch. Int. Med.* 66: 787 (Oct.) 1940.

mental results, Williams and his associates suggest that thiamine deficiency, as it exists in sections where beriberi and pellagra are uncommon, should be looked for principally in that group of patients whose condition has been diagnosed as neurasthenia.

In the experiments of Williams and his collaborators a dietary supply of 0.95 mg. of thiamine (285 U. S. P. units) was not associated with evidence of nutritional deficiency in the persons studied. Nevertheless, this amount was apparently not adequate for the best nutritional state of the patient, for greater allowances of thiamine resulted in an increase in alertness and attentiveness of experimental subjects and permitted a more satisfactory performance of these subjects with an exercising device. Unfortunately, this conclusion was based on limited experimental data; an extension of this phase of the investigation would be of great practical value. Experiments carried out during the winter and summer seasons indicated that symptoms of thiamine deficiency developed earlier among those whose diets were restricted during the winter months. This indication that a climatologic factor may influence the rate of development of evidence of thiamine deficiency would also seem to merit further study.

The type of investigation discussed in the foregoing paragraphs furnishes a more exact knowledge of the symptoms encountered as a result of the lack of particular dietary ingredients. A deficiency disease such as pellagra, scurvy or beriberi, as observed clinically, does not ordinarily represent an uncomplicated deficiency of a single dietary factor. It is only by controlled experimental investigations that the precise role of any particular vitamin in human nutrition can be determined.

Current Comment

HISTOPLASMOSIS

At relatively infrequent intervals since 1905, cases of histoplasmosis have been reported in the American literature. In that year Samuel Taylor Darling described three cases with a clinical picture somewhat similar to kala-azar but with tissues containing the organism which he named *Histoplasma capsulatum*. In a recent review of the subject Meleney¹ discusses thirty-two cases of the disease, thirteen of which have not yet been reported in the literature and twenty-two of which were recorded in the continental United States. The disease should be suspected, Meleney points out, in patients presenting a wide variety of clinical symptoms and signs. Any condition characterized by enlargement of the liver and spleen, by generalized or regional enlargement of the lymph nodes, by an aplastic or undiagnosed secondary type of anemia or leukopenia, by generalized or localized abscesses or ulcers of the skin or by chronic pulmonary infections should lead one to suspect histoplasmosis. In advanced systemic infec-

tions the organisms may be found in thin smears of the peripheral blood or in dehemoglobinized thick drops similar to those used for the diagnosis of malaria. Spleen, liver, lymph node or sternal puncture may reveal the organisms and a careful examination of sputum may show their presence. Animal inoculation and cultivation have been of diagnostic value. Therapy has not proved especially effective but Meleney believes that antimony preparations should receive particular attention. The disease appears to be widely distributed throughout the world and will doubtless be recognized with increasing frequency in the future. Its close resemblance to kala-azar in clinical symptomatology presents a problem which requires considerable diagnostic acumen to penetrate.

COLD PREPARATIONS UNDER COLD SCRUTINY

On February 3 W. G. Campbell, Commissioner of Food and Drugs of the Food and Drug Administration, notified all manufacturers of "cold" preparations that henceforth this class of products will be included in the administration's program of operations. The announcement pointed out that present day medical opinion supports the view that there is no known substance or mixture of substances which can be relied on to prevent or cure colds; further, that surveys of products which now appear on the market show that many of them make claims that involve the treatment or prevention of colds which are not justified by the scientific facts, while others exaggerate the effects which the medications will have on the symptoms; and finally, now that section 201 (n) of the Food, Drug and Cosmetic Act is fully effective, in the opinion of the administration any reference to colds in the labeling of a drug should clearly indicate just what the effects of the medicine with respect to this disease condition will be and, if necessary to avoid misunderstanding, just what the limitations of the medication are. The commissioner bases this on the fact that section 201 (n) requires that the label reveal any facts that are material in the light of such affirmative representations as the label may make. By way of explanation, the notice includes a statement to the effect that, for various reasons, one of which has been lack of adequate facilities, the Food and Drug Administration has not in the past given attention to the large number of preparations sold for the treatment or prevention of colds or for the mitigation of the symptoms of this disease, but that henceforth this class of products will be included in the administration's program of operations. Recently THE JOURNAL called attention to the promotion of one line of these preparations in which it was suggested that the druggist prescribe such items for the treatment of the active cold. This illustrated the extent to which manufacturers of these preparations have gone in promoting them to the public. Now that the Food and Drug Administration has determined to review the claims made it will be exceedingly interesting to watch the changes which will take place in the claims which are made for many of these preparations.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

PLANS FOR COORDINATION

Federal Security Administrator Paul V. McNutt has announced appointment of an interdepartmental advisory committee, composed of officials of various federal agencies working in the fields of health and welfare, to assist and advise him in coordinating all health, medical care, welfare, nutrition, recreation and related activities affecting national defense.

The administrator said that the field staffs of various governmental agencies would also play an important part in securing effective coordination of these programs. He explained that he had established twelve federal regional advisory councils made up of the field representatives of all federal agencies participating in these activities and that he had designated the twelve regional directors of the Social Security Board as regional defense coordinators.

These coordinators, he said, will act as chairmen of the regional advisory councils and maintain the relationships in these fields with the state defense councils in their respective regions.

Mr. McNutt declared that he was now setting up a small staff within his office to assist him and Assistant Coordinator Charles P. Taft to coordinate health and welfare and related defense activities. This staff is headed by Miss Gay Shepperson, former work project administrator for Georgia.

The federal agencies and their representatives composing the interdepartmental advisory council include Arthur Altmeyer, chairman, Social Security Board; Aubrey Williams, administrator, National Youth Administration; J. J. McEntee, director, Civilian Conservation Corps; J. W. Studebaker, director, Office of Education; Dr. Warren Draper, Acting Surgeon General, Public Health Service; C. B. Baldwin, administrator, Farm Security Administration; M. L. Wilson, director, Extension Work; Milo Perkins, administrator, Surplus Marketing Administration; Dr. Louise Stanley, chief, Bureau of Home Economics; John M. Carmody, administrator, Federal Works Agency; Howard O. Hunter, acting commissioner, Work Projects Administration; Frances Perkins, secretary of labor; Katherine Lenroot, chief, Children's Bureau; Conrad Wirth of the National Park Service; Harold W. Breining, assistant administrator, Veterans Administration; Charles W. Eliot, director, National Resources Planning Board, and the following members from the Advisory Commission to the Council of National Defense: Frank Bane, director, Division of State and Local Cooperation; Charles Palmer, housing coordinator; J. B. Hutson, agriculture division; Sidney Hillman, labor division, and Harriet Elliott, Consumer Protection Division.

ASSISTANCE OF THE AMERICAN MEDICAL ASSOCIATION IN CLASSIFICATION AND PROCUREMENT OF PHYSICIANS FOR MILITARY SERVICE

The Adjutant General of the Army has sent the following instructions to the Surgeon General and to each corps area and department commander:

1. The following plan has been approved and will be placed in operation at such time as the War Department may direct.

(a) The American Medical Association will prepare and maintain a roster of civilian physicians, classified as to professional specialties and proficiency, who have agreed to accept commissions in the Army of the United States when needed for immediate active duty during a national emergency.

(b) The Surgeon General will designate one or more medical officers of the Regular Army who will be placed on duty at Headquarters, Sixth Corps Area, as representatives of his office in all matters pertaining to the Medical Corps Reserve and the American Medical Association.

(c) Corps area commanders will report, at times specified by the War Department, the number of Medical Corps Reserve officers under their assignment jurisdiction who are available for active duty.

(d) Vacancies in allotments made to any corps area by the War Department that cannot be filled by the detail of a qualified Reserve officer under the assignment jurisdiction of the corps area commander will be promptly reported to the War Department, which will cause them to be filled from Medical Corps Reserve officers in the Army and Service Assignment group, or by adding these vacancies to the allotment of other corps areas having a surplus.

(e) If no qualified Reserve officer can be found, the Surgeon General will notify his representative at Headquarters, Sixth Corps Area, as to the qualifications desired and the location and grade of the vacancy. The representative will then secure recommendations from the American Medical Association and forward all information to the appropriate corps area commander, notifying the War Department of the action taken. The corps area commander will immediately cause the candidate to be given a physical examination and, if found qualified, will secure from the applicant a properly completed application for commission (W. D., A. G. O. form 170). All papers will then be forwarded to the Adjutant General for final action by means of air mail and "Immediate Action" stationery when necessary.

(f) Corps area commanders are not authorized to grant waivers for physical defects in these instances but may reject a candidate when found physically disqualified, notifying the Adjutant General of the action taken.

(g) On receipt of a properly executed oath of office, the corps area commander will cause orders to be issued placing the appointee on immediate active duty.

(h) No appointments will be made under this authority of applicants over 55 years of age.

(i) The appearance of the candidate before an examining board as prescribed in AR 140-5 will be waived in these cases.

2. The Surgeon General and corps area and department commanders will complete all arrangements necessary to place the plan in operation without delay when directed by the War Department.

ROTATION OF NATIONAL GUARD AND RESERVE MEDICAL DEPARTMENT OFFICERS

The Adjutant General of the Army has sent the following memorandum to the commanding generals of all armies and the commanding generals of all corps areas:

1. On receipt of individual applications and with the approval of all commanders concerned, Reserve and National Guard Medical Department officers, after approximately six months' duty with its fixed installations, may be afforded an opportunity to attend a one month refresher course at the Medical Field Service School with a view to subsequent assignment to medical field or tactical units. Subject to the same conditions, Reserve and National Guard Medical Department officers, after approximately six months' duty with field or tactical units, may receive a one month refresher course at certain general hospitals, with subsequent assignment to fixed medical installations.

2. Subject to the approval of all commanders concerned, Medical Department commissioned personnel may be rotated within regimental medical detachments and between regimental medical detachments and medical battalions, squadrons and regiments.

3. However, the procedure authorized in paragraphs 1 and 2 must not interfere with or be detrimental to the balanced training of National Guard units, so prescribed that they may be prepared to take the field on short notice.

NEW INSTRUCTIONS GOVERNING PHYSICAL EXAMINATIONS FOR RESERVE AND NATIONAL GUARD OFFICERS

Additional instructions governing the physical examination of reserve officers and National Guard officers ordered to active duty for periods of more than thirty days were announced on January 17 by the War Department.

According to the new instructions, only one examination is prescribed or authorized for each officer to determine his physical qualification for extended active duty. This examination, however, carries with it the right of appeal in certain cases. It may be given not more than sixty days prior to the effective date of each officer's active duty or after he has reported for such active duty, subject to the following provisions:

1. Examination prior to actual entry on active duty will be made at the option and on the request of the individual concerned, and without expense to the federal government for travel or pay.

2. A National Guard officer not examined prior to induction, as authorized, will be examined at the earliest practicable date following induction. If it is not practicable to give such an examination before he departs from his home station, the examination will be deferred until his arrival at his unit training center or other station where the necessary medical personnel and facilities are available, and in any event within the first thirty days of active duty. In such cases the commanding general of the corps area or department of origin will notify the army commander concerned, who will arrange with the commanding general of the corps area or department of destination for the necessary examination.

3. A reserve officer not examined prior to entry on active duty will be ordered to active duty without a prior physical examination. If he is to be permanently assigned to a station in his corps area or department of residence not more than 500 miles distant from his home, and if his station has the necessary medical personnel and equipment to make physical examinations of the type prescribed by army regulations, he will be ordered to proceed directly to his permanent station where the physical examination will be given. If the officer's first permanent assignment is to be (a) a station outside the corps area or department of his home, (b) a station more than 500 miles from his home or (c) a station within the corps area or department of his home but one at which personnel and equipment required for physical examination are not available, he will be assigned to his permanent station but ordered to proceed on temporary duty to the nearest army station, where the physical examination prescribed by army regulations can be made; if found physically qualified, he will then proceed to his permanent station in compliance with original orders. In any event, the physical examination shall be completed within the first thirty days of active duty.

To be acceptable, examinations prescribed by army regulations, whether made prior to or after entry on active duty, must be made at an army medical installation where professional specialists and proper facilities are available for complete physical examination.

The examinations prescribed by army regulations will be made by boards of three or more medical officers, at least one of whom shall be an officer of the Medical Corps of the Regular Army. If practicable, in the examination of National Guard officers at least one member of the board will be a medical officer of the National Guard of the United States and, if practicable, in the examination of reserve officers at least one member of the board will be a reserve medical officer.

Physical standards for all active duty are those prescribed in AR 40-100, AR 40-105 and, in addition, for the Air Corps in AR 40-110, except as modified for certain officers of the National Guard who were commissioned or examined and found qualified for federal recognition or appointment in the National Guard of the United States prior to July 2, 1940.

Examination to determine physical qualification for extended active duty will include a roentgenogram of the chest, a serologic test for syphilis and a urine examination, including microscopic examination. An electrocardiogram will be made if the officer is 50 years of age or older, if the officer is 45 years of age or older and is required by assignment or orders to participate regularly in airplane flights, or if in the opinion of the medical examiner such examination is indicated.

Corps area and department commanders except in cases expressly reserved by the War Department are authorized to make final determination of the physical qualification of individual officers without reference to the War Department, except in cases involving physical fitness for flying. Action in the latter cases will be as prescribed in AR 40-110.

They are authorized also to grant waivers for physical defects when the interest of the government or of the military service is not compromised, provided the defects will not interfere with the satisfactory performance of duties appropriate to the grade of the individual concerned and are not likely to be aggravated as a result of active military service. In certain other cases waivers will be granted only on the written request of the affected individual, and in such cases pertaining to National Guard officers the recommendation of the division or separate unit commander concerned will also be necessary. Each request for the latter type of waiver must be accompanied by an affidavit from the individual concerned acknowledging that the physical defects on which waiver is requested existed prior to entry into active military service, and that they were not the result of such service.

Only the War Department and corps area and department commanders are authorized to adjudge an officer physically disqualified for extended active duty, and only these authorities may authorize his relief from extended active duty for physical disqualification. Similarly, only these authorities may adjudge an officer physically qualified for active duty.

National Guard officers found to be disqualified as a result of physical examination prior to induction, and whose federal recognition is not withdrawn by that date, will be relieved from active duty on the effective date of such induction, on orders issued by the corps area or department commander.

If found to be disqualified as a result of physical examination subsequent to induction, National Guard officers will be relieved from active duty on determination of disqualification, on orders issued by the army, corps area or department commander.

If found to be physically disqualified, National Guard officers thereupon become subject to withdrawal of federal recognition and termination of commission in the National Guard of the United States. Such withdrawal and termination will be accomplished by the War Department.

Reserve officers found to be physically disqualified as a result of physical examination prior to the effective date of active duty, will not be ordered to extended active duty. If found to be physically disqualified as a result of physical examination subsequent to the effective date of active duty, they will be returned to their homes and relieved from active duty.

An officer already on extended active duty who is reported as physically disqualified by the board which conducted the examination of the type specified by army regulations will be retained on active duty pending decision on appeal, if request for appeal is made, or on request for waivers, if any.

To handle appeals, each corps area and department commander will convene as many medical appeal boards as he deems necessary. Such boards will consist of two or more medical officers of mature experience and judgment, other than those comprising the examination boards convened according to army regulations to physically examine officers.

If the physical examination of the type prescribed in army regulations discloses disqualifying defects, the officer will be so informed by the corps area or department commander in whose jurisdiction the National Guard or reserve officer was examined. This notice will announce the specific defects which indicate that the officer is physically disqualified for active duty. He will be advised in the same communication of his

right to appeal from the findings of the board which conducted the physical examination, provided, if the officer is not on extended active duty, that he is willing to defray from personal funds the cost of travel involved in appearing before the appeal board and his subsistence in hospital, if hospitalization is involved in the appeal examination.

In considering appeals, a medical appeal board will limit its examination to the disqualifying defects reported by the examining board. Medical appeal boards are without authority to extend their examinations beyond these defects. When practicable, applicants will be ordered before an appeal board at a hospital or dispensary other than the one in which they were originally examined.

The right of appeal is retroactive to include all National Guard and reserve officers who have been found to be disqualified physically for extended active duty since Sept. 6, 1940, provided, if the officer is now on an inactive status, that the reexamination be made without expense to the government for travel and pay, and provided, further, that the individual concerned has not subsequently been discharged from the National Guard of the United States or the Officers' Reserve Corps, as the case may be.

Except as to flying officers and as to officers whose cases have been expressly reserved by the War Department, action of the corps area or department commander on recommendations of medical appeal boards will be final.

A reserve officer who receives a physical examination of the type prescribed by army regulations prior to the effective date of his extended active duty, and who reports for active duty within sixty days thereafter, will be given a physical examination, as required by Public Resolution 96, Seventy-Sixth Congress, to determine defects arising from intervening illness or injury since the prior complete examination.

Each such examinee will exhibit to the medical examining board his copy of the report of prior examination and will also furnish the board a certificate in duplicate that he has or has not suffered an illness or injury since the date of the prior examination. The certificate will indicate in detail the nature and extent of any intervening illness or injury.

When required, examinations to determine physical defects arising from intervening illness or injury will be made at the earliest practicable date after the officer concerned has arrived at his permanent station, and in any event within the first thirty days of active duty. Such examinations will be made by one or more medical officers of the Army of the United States.

An officer, examined within sixty days prior to actual entry upon active duty, and found physically qualified for such duty, will not be relieved from or rejected for active duty because of anything found in the examination to determine intervening disease or injury, except as follows:

If, because of intervening illness or injury, the officer concerned is unable to report in person to the place designated in his active duty or induction orders, he will be examined at the place where he is confined by illness or injury. Final disposition of the cases of such officers will be made by corps area and department commanders after consideration of the report of the medical officer or medical board who conducted the examination. The same examination shall be made and the same action taken with respect to an officer, previously not examined, who because of injury or illness is unable to report to the station and at the time indicated in the orders directing his extended active duty.

If the officer who has reported in person to the designated place for active duty is considered to have a disqualifying defect, he will be ordered to an army general hospital, and if found thereafter by a disposition board to be physically disqualified for active duty, he will be relieved from active duty by the corps area or department commander, or, in appropriate cases he will, on approval of the War Department, be brought before an army retiring board in accordance with the provisions of the Act of April 3, 1939. If approved findings of the disposition board determine that the officer is physically qualified for active duty, he will be ordered to his organization for duty.

SURGEON GENERAL'S OFFICE MOVED

The office of the Surgeon General of the Army has just been moved from the War Department Annex No. 1 at 401 Twenty-Third Street N.W., Washington, D. C., to the Social Security Building, Fourth and C streets S.W., where the offices of the Ordnance Department are located.

NEW COMMANDANT AT NAVY MEDICAL CENTER

Rear Admiral Charles M. Oman, Medical Corps, U. S. Navy, has been assigned to command the Navy Medical Center in Washington, D. C., relieving Rear Admiral Harold W. Smith, who takes over the duties of inspector of medical activities for the Atlantic Coast, with station in the Bureau of Medicine and Surgery in Washington.

EIGHTEEN BRANCHES OF SCHOOL OF AVIATION MEDICINE

The War Department has established at various Air Corps stations in the United States, Hawaii and the Panama Canal Zone eighteen branches of the School of Aviation Medicine at Randolph Field, Texas. Branches were established to provide the practical training of officers of the medical reserve corps who have satisfactorily completed the extension course of the School of Aviation Medicine and who are candidates for graduation as aviation medical examiners. The central School of Aviation Medicine at Randolph Field was founded to train medical officers in the principles of examination of aviators and in the aviation specialties such as ophthalmology, cardiology and neuropsychiatry, and in the administration of the medical department as related to special requirements of the Air Corps.

CONTRIBUTIONS FOR MEDICAL SUPPLIES FOR GREECE

Dr. Haven Emerson, New York, chairman of the American Physicians Committee to Aid Greece, said on January 29 that shipments of medical supplies to Greece will have to be stepped up if a major health calamity is to be avoided in that country. A dispatch from the executive officer of the American Red Cross in Greece, Charles A. House, who had made a tour of the regions behind the front, reported that, while local authorities were doing everything in their power to care for the sick and wounded, the scope for further aid from America was enormous and all manner of surgical equipment was badly needed. Dr. Emerson said there has been a decided falling off in the last few weeks in the amount of contributions received for sending medical and surgical supplies to Greece and that during the last week the Medical and Surgical Supply Committee of America, 420 Lexington Avenue, New York City, had shipped only \$7,368 worth of such supplies to Athens, as compared to previous shipments of over \$10,000 each.

INDUSTRIAL HYGIENE PROGRAMS AND UNITS

The Division of Industrial Hygiene of the U. S. Public Health Service is preparing to assist in the prevention and control of health hazards in government arsenals and navy yards. The Surgeon General has authorized the Division of Industrial Hygiene to employ additional personnel to organize industrial hygiene programs and to train personnel within these military establishments to carry out the programs.

The Surgeon General has also authorized the Division of Industrial Hygiene to assign several units, each consisting of a doctor and an engineer, to cooperate with state industrial hygiene units in giving special attention to airplane and munitions plants and to shipyards. The Vermont unit is now receiving assistance in the investigation of health problems which have arisen in the machine tool industry as a result of inadequate housing, long hours of work and certain foundry hazards. State industrial hygiene units are urged to inform the Division of Industrial Hygiene of their most immediate defense problems and to make suggestions which may be helpful to other units.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY

SECOND CORPS AREA

The following additional medical reserve corps officers had been ordered to active duty by the Commanding General, Second Corps Area, up to February 7. The Second Corps Area comprises the states of New York, New Jersey and Delaware.

BANDES, Joseph, 1st Lieut., New York, Fort Dix, N. J.
BRODEY, Adrian, 1st Lieut., Far Rockaway, N. Y., Carlisle Barracks, Pa.
COHEN, William, 1st Lieut., Trenton, N. J., Fort Benning, Ga.
CORVIN, Emanuel M., 1st Lieut., New York, Fort Hamilton, N. Y.
DELNEGRO Albert E., 1st Lieut., Newark, N. J., Savanna Ordnance Depot, Savanna, Ill.
DIENER, Samuel, 1st Lieut., Newark, N. J., Fort Benning, Ga.
DUTTO, Bartholomew J., 1st Lieut., Kingston, N. Y., Camp Livingston, La.
ENGLE, Jerome W., 1st Lieut., Yonkers, N. Y., Fort Dix, N. J.
EVANS, Alexander L., 1st Lieut., Willard, N. Y., Fort Ontario, N. Y.
GILNER, Abraham, 1st Lieut., New York, Fort Constitution, N. H.
GIORGINI, Gino L., 1st Lieut., Copiague, N. Y., Fort Dix, New Jersey.
GLICK, Louis J., 1st Lieut., New Rochelle, N. Y., Fort Dix, N. J.

FOURTH CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Fourth Corps Area, which comprises the states of Tennessee, North Carolina, South Carolina, Alabama, Georgia, Mississippi, Florida and Louisiana:

BARNES, Justus M., Captain, Montgomery, Ala., Camp Wheeler, Ga.
BELL, Francis E., 1st Lieut., Palatka, Fla., Camp Davis, N. C.
BILLINGHURST, George A., 1st Lieut., Milledgeville, Ga., Camp Wheeler, Ga.
BOSTICK, John N., 1st Lieut., Gilbert, La., Camp Wheeler, Ga.
BOWEN, Lucius M., 1st Lieut., Waverly, Tenn., Fort Bragg, N. C.
BROWN, Harry G., 1st Lieut., Natchez, Miss., Camp Wheeler, Ga.
CRANKSHAW, Daune W., Major, Burton, N. C., Fort Benning, Ga.
DIETRICH, Julius, 1st Lieut., Crossville, Tenn., Camp Forrest, Tenn.
DUSENBERRY, James F., 1st Lieut., Laurens, S. C., Fort Jackson, S. C.
EDWARDS, Franklin D., Captain, Columbus, Ga., Camp Wheeler, Ga.
FOLSOM, Charles W., 1st Lieut., Miami, Fla., Camp Wheeler, Ga.
GALLIS, Anthony H., 1st Lieut., Atlanta, Ga., Fort Benning, Ga.
GOLDEN, William C., 1st Lieut., Clanton, Ala., Camp Davis, N. C.
HAMILTON, Andros S., 1st Lieut., Monroe, La., Camp Claiborne, La.
HOUSER, Frank M., 1st Lieut., Macon, Ga., Camp Wheeler, Ga.
JORDAN, Henry C., Captain, Robertsdale, Ala., Fort Bragg, N. C.
KISNER, Wendell H., 1st Lieut., Baton Rouge, La., Camp Croft, S. C.
LAMAR, Carlos A. P., 1st Lieut., Miami, Fla., Camp Wheeler, Ga.
MANNING, William S., Lieut. Col., Jacksonville, Fla., Jacksonville, Fla.
MILLING, Chapman J., 1st Lieut., Columbia, S. C., Fort Jackson, S. C.
MITCHELL, William B., 1st Lieut., Trion, Ga., Fort McClellan, Ala.

SIXTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Sixth Corps Area. The Sixth Corps Area comprises the states of Wisconsin, Illinois and Michigan.

ALBAUM, Joseph, 1st Lieut., Lincoln, Ill., Illinois Induction Board.
ALLEN, Elmer S., 1st Lieut., Arcola, Ill., 2d Medical Battalion, Fort Sam Houston, Texas.
APPEL, Ben Arthur, 1st Lieut., Standish, Mich., Illinois Induction Board.
BARON, Benzoim C., Captain, Munising, Mich., Armored Forces, Fort Benning, Ga.
BENSON, George, 1st Lieut., Richland Center, Wis., Armored Forces, Fort Benning, Ga.
BERNSTEIN, Max M., 1st Lieut., Chicago, Station Hospital, Camp Grant, Ill.
BOALS, Robert T., 1st Lieut., Detroit, William Beaumont General Hospital, El Paso, Texas.
BROSIN, Henry W., 1st Lieut., Chicago, Station Hospital, Fort Custer, Mich.
CARY, Erwin C., Captain, Reedsville, Wis., Armored Forces, Fort Benning, Ga.
DEL BECCARO, Edward V., Major, Chicago, Station Hospital, Fort Sam Houston, Texas.
DROEGE, Edward H., Captain, Granite City, Ill., Armored Forces, Fort Benning, Ga.
FAVUS, Irving, 1st Lieut., Chicago, 61st C. A., Fort Sheridan, Ill.
FELDMAN, Emanuel, 1st Lieut., Bayonne, N. J., 5th Division, Fort Custer, Mich.
FELDMAN, Harold, Captain, Pekin, Ill., Armored Forces, Fort Benning, Ga.
FILEK, Allan, Captain, Green Bay, Wis., Armored Forces, Fort Benning, Ga.
FISHER, Seymour, Captain, Springfield, Ill., Station Hospital, Fort Sheridan, Ill.

GOODWIN, Edward M., 1st Lieut., New York, Fort Hamilton, N. Y.
KOLBE, Joseph T., 1st Lieut., Mount Vernon, N. Y., Camp Upton, N. Y.
KOPET, Sidney J., 1st Lieut., Brooklyn, Camp Livingston, La.
LEIDER, Sydney, 1st Lieut., Brooklyn, Fort Devens, Mass.
LEVER, Shelby M., 1st Lieut., Brooklyn, Fort Devens, Mass.
LITTER, Leo, 1st Lieut., New York, Fort Hancock, N. J.
MAISEL, Irving, 1st Lieut., Newark, N. J., Savanna Ordnance Depot, Savanna, Ill.
MARKOWITZ, Isidor, Captain, Brooklyn, Army Recruiting Station, Newark, N. J.
METZ, Henry, 1st Lieut., Hackensack, N. J., Fort Dix, N. J.
OFFENKRANTZ, Frederick M., 1st Lieut., Newark, N. J., Fort Jay, N. Y.
ORANSKY, Marvin, 1st Lieut., Newark, N. J., Fort Benning, Ga.
PIERCE, Henry A., 1st Lieut., Leonia, N. J., Fort Dix, N. J.
RUGGIERO, Wilfred F., 1st Lieut., New York, Carlisle Barracks, Pa.
SCHMESING, Clifford A., 1st Lieut., Salamanca, N. Y., Fort Niagara, N. Y.
SCHWARTZ, Louis, 1st Lieut., New York, Fort Devens, Mass.
SHAPIRO, Morris A., 1st Lieut., Schenectady, N. Y., West Point, N. Y.
TURANO, William M., 1st Lieut., New York, Fort Hamilton, N. Y.
WARRES, Herbert L., 1st Lieut., Brooklyn, Fort Devens, Mass.
WEISS, Henry W., 1st Lieut., Ellenville, N. Y., Fort Devens, Mass.

NEW, James S., 1st Lieut., Milledgeville, Ga., Camp Davis, N. C.
POOLE, Everett B., Captain, Greenville, S. C., Camp Croft, S. C.
RINAMAN, James C., Captain, Miami, Fla., Camp Wheeler, Ga.
ROBINSON, Melvin D., 1st Lieut., Greenwell Springs, La., Camp Croft, S. C.
SMITH, James S., Captain, Miami, Fla., Camp Wheeler, Ga.
SNELLING, William R., 1st Lieut., Columbus, Ga., Fort McClellan, Ala.
STAMM, Joseph, 1st Lieut., New Orleans, Camp Wheeler, Ga.
TISDALE, Albert A., 1st Lieut., LaFayette, La., Camp Croft, S. C.
TUGWELL, Wilton E., 1st Lieut., Pensacola, Fla., Fort Bragg, N. C.
WILLIAMS, Charles R., 1st Lieut., Wadley, Ga., Camp Croft, S. C.
WILSON, Richard A., 1st Lieut., Wilmington, N. C., Fort Devens, Mass.
WITHERINGTON, Albert S., Jr., 1st Lieut., DeQuincy, La., Camp Wheeler, Ga.

Orders Revoked

The following officers, previously reported, have been relieved from duty or their orders have been revoked:

BATES, Thomas H., Major, Lake City, Fla.
FISHER, Roy A., Jr., 1st Lieut., Knoxville, Tenn.
GIBSON, Rac B., 1st Lieut., Greeneville, Tenn.
GOLDEN, William C., 1st Lieut., Clanton, Ala.
GRIFFIN, James C., 1st Lieut., Tampa, Fla.
LEA, Joseph D., 1st Lieut., Baton Rouge, La.
NEILL, Francis K., 1st Lieut., Albany, Ga.
NUNGESTER, Garrold H., 1st Lieut., Decatur, Ala.
PALMER, Yates S., 1st Lieut., Valdese, N. C.
WARD, Albert L., 1st Lieut., Fort St. Joe, Fla.
WORLEY, Wyeth B., 1st Lieut., Shreveport, La.

FOLEY, Mark E., 1st Lieut., St. Nazianz, Wis., 5th Division, Fort Custer, Mich.
FRACKELTON, William H., 1st Lieut., Milwaukee, William Beaumont General Hospital, El Paso, Texas.
HAGELSHAW, Gayland L., Major, Bay City, Mich., Fitzsimons General Hospital, Denver.
HOLDEN, Alwin J., Lieut. Col., Chicago, Station Hospital, Fort Sam Houston, Texas.
HOLT, Henry T., Captain, Detroit, 5th Division, Fort Custer, Mich.
HUBBLE, William F., 1st Lieut., Decatur, Ill., 1st Medical Battalion, Fort Bliss, Texas.
JOHNSON, Henry C., Major, Madison, Wis., Station Hospital, Camp Grant, Ill.
KENNEDY, Richard L., 1st Lieut., Chicago, Puerto Rican Department.
KOCOVSKY, Elmer C., 1st Lieut., Milwaukee, Reception Center, Camp Grant, Ill.
LUM, Thomas K., Captain, Danville, Ill., Fort Benning, Ga.
MACINTYRE, Dugald S., 1st Lieut., Ann Arbor, Mich., William Beaumont General Hospital, El Paso, Texas.
MAMMOSER, Lambert F., Captain, Chicago, Station Hospital, Fort Sheridan, Ill.
MARKUS, Erwin H., 1st Lieut., Eloise, Mich., Replacement Center Dispensary, Camp Grant, Ill.
MARTINI, Henry F., 1st Lieut., Wausau, Wis., 5th Division, Fort Custer, Mich.
McCORMACK, Edward A., 1st Lieut., Niagara, Wis., 123d Field Artillery, Monmouth, Ill.
MIDDLETON, William D., Major, Hayward, Wis., Fort Sam Houston, Texas.
MOKROHAJSKY, Stephen M., 1st Lieut., Green Bay, Wis., Station Hospital, Camp Grant, Ill.
MYERS, William H., Captain, Coal Valley, Ill., Armored Forces, Fort Benning, Ga.
OXMAN, Emanuel M., 1st Lieut., Kankakee, Ill., Replacement Center Dispensary, Camp Grant, Ill.

POWELL, Harry I., 1st Lieut., Chicago, Replacement Center Dispensary, Camp Grant, Ill.
QUANDT, Eberhardt H., Captain, Rockford, Ill., Station Hospital, Camp Grant, Ill.
RAGUE, Paul O., 1st Lieut., Manchester, Mich., 5th Division, Fort Custer, Mich.
RANSOM, Gilbert T., 1st Lieut., Fairfield, Ill., 123d Field Artillery, Monmouth, Ill.
RECHLICZ, Ervin T., 1st Lieut., Milltown, Wis., Armored Forces, Replacement Center, Fort Knox, Ky.
REID, Wesley G., Major, Detroit, Armored Forces, Fort Benning, Ga.
RICHMAN, Samuel H., Lieut. Col., Rock Island, Ill., Station Hospital Fort Custer, Mich.
RUBOVITS, Frank E., Jr., 1st Lieut., Chicago, Armored Forces, Fort Benning, Ga.
RYAN, John A., 1st Lieut., Ann Arbor, Mich., Armored Forces, Fort Benning, Ga.
SEGENREICH, Harry M., 1st Lieut., Manteno, Ill., Armored Forces, Fort Benning, Ga.
SHEAGREN, John W., 1st Lieut., Rockford, Ill., Station Hospital, Camp Grant, Ill.
SMITH, Harvey S., 1st Lieut., East St. Louis, Ill., 123d Field Artillery, Monmouth, Ill.
SPIRA, Samuel B., 1st Lieut., Chicago, Armored Forces, Fort Benning, Ga.

STEINHOFF, Carl F., Major, Chicago, Letterman General Hospital, San Francisco.
STONE, Grant C., 1st Lieut., Berlin, Wis., Reception Center Dispensary, Camp Grant, Ill.
SUGAR, HYMAN S., 1st Lieut., Chicago, 5th Division, Fort Custer, Mich.
SWEENEY, Leo P. A., Captain, Chicago, Reception Center, Camp Grant, Ill.
TULSKY, Alex S., 1st Lieut., Chicago, Armored Forces, Fort Benning, Ga.
WALTER, Jacob, 1st Lieut., Chicago, Reception Center, Camp Grant, Ill.
WIER, John S., Captain, Fond Du Lac, Wis., Armored Forces, Fort Benning, Ga.
WILLIAMS, Francis R., 1st Lieut., Detroit, Station Hospital, Camp Grant, Ill.
WILLIAMSON, William P., 1st Lieut., Detroit, Armored Forces, Fort Benning, Ga.
WILTRAKIS, George A., Captain, Chicago, Station Hospital, Camp Grant, Ill.
WINKLER, Raymond J., 1st Lieut., Hilbert, Wis., Armored Forces, Fort Benning, Ga.
ZINN, August K., 1st Lieut., Battle Creek, Mich., Replacement Center Dispensary, Camp Grant, Ill.

SEVENTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Seventh Corps Area (North Dakota, South Dakota, Minnesota, Nebraska, Iowa, Kansas, Missouri, Arkansas and Wyoming).

BREDALL, Jerome Julian, Captain, Perryville, Mo., Camp J. T. Robinson, Ark.
DWORAK, Henry Louis, 1st Lieut., Omaha, Fort Ord, Calif.
HAGERBUSCH, Omer Ernst, 1st Lieut., University City, Mo., William Beaumont General Hospital, El Paso, Texas.
HARRELL, William Bedwell, Jr., 1st Lieut., Little Rock, Ark., Camp J. T. Robinson, Ark.
HOVER, Galen Monroe, Captain, Fort Riley, Kan., Fort Riley, Kan.
JONES, Otey Sherman, Captain, St. Louis, Fort Lewis, Wash.
KLOESS, Edward John, Captain, Leadwood, Mo., Jefferson Barracks, Mo.
LIPTON, MORRIS L., Captain, Rosebud, S. D., Fort Ord, Calif.
LYONS, Virgle E., 1st Lieut., North Little Rock, Ark., Fort Ord, Calif.

PERRINGS, Fred Selby, Major, St. Louis, Fort Omaha, Neb.
PHILLIPS, Bert Lee, 1st Lieut., Bauxite, Ark., Fort Ord, Calif.
PORTER, Alfred Lamar, 1st Lieut., Van Buren, Ark., Fort Ord, Calif.
QUICK, David William, Jr., 1st Lieut., Dayport, Minn., Fort Leonard Wood, Mo.
QUIGLEY, Maurice Werling, Lieut. Col., Minneapolis, Camp J. T. Robinson, Ark.

Orders Revoked

BARRY, Gerald Williams, 1st Lieut., Kansas City, Mo., Fort Ord, Presidio of Monterey, Calif.
BROWN, William, 1st Lieut., Paola, Kan., Fort Lewis, Wash.
DWORAK, Arthur Francis, Captain, St. Paul, Fort Bliss, Texas.
FELLMAN, Abe C., 1st Lieut., Omaha, Camp Murray, Wash.
LARSON, Marvin Oliver, 1st Lieut., Hawarden, Iowa, Camp J. T. Robinson, Ark.
OLSON, William Emanuel, 1st Lieut., Des Moines, Iowa, Fort Lewis, Wash.
WETRICH, Max Franklin, 1st Lieut., West Des Moines, Iowa, Camp Grant, Ill.

EIGHTH CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Eighth Corps Area. The Eighth Corps Area comprises the states of Colorado, Arizona, New Mexico, Oklahoma and Texas.

BEAL, Wendell E., 1st Lieut., Pearsall, Texas, Fort Sam Houston, Texas.
DAVIS, Frank Milton, Major, San Antonio, Texas, Station Hospital, Camp Wolters, Texas.
DUBOE, Sidney Harvey, 1st Lieut., Phoenix, Ariz., Fort Sill, Okla.
ETTER, Edward F., Captain, Sherman, Texas, Fort Sam Houston, Texas.
GADDIS, Herman W., 1st Lieut., Corpus Christi, Texas, Fort Sam Houston, Texas.
HUDSON, Isaac Frederick, Captain, Stamford, Texas, Fort Sam Houston, Texas.
JONES, William Edgar, 1st Lieut., Mesquite, Texas, Fort Sam Houston, Texas.
OSBORNE, Clarence Fred, Captain, Pasadena, Texas, Fort Sam Houston, Texas.
PATTILLO, Albert Dixon, Captain, Wichita Falls, Texas, Fort Sam Houston, Texas.

PHILLIPS, Clairice M., Captain, Levelland, Texas, Fort Sam Houston, Texas.
PRESTON, Thomas K., 1st Lieut., Mimbres, N. M., Fort Sam Houston, Texas.
ROBERTSON, David Lyle, 1st Lieut., Wichita Falls, Texas, Fort Sam Houston, Texas.
ROWELL, Robert C., 1st Lieut., Rusk, Texas, Fort Sam Houston, Texas.
SALLEY, Colvin W., 1st Lieut., Baytown, Texas, Fort Sam Houston, Texas.
STANTON, William Paul, 1st Lieut., San Antonio, Texas, Fort Sam Houston, Texas.
TRIPPET, Horace H., 1st Lieut., Waco, Texas, Fort Sam Houston, Texas.

Orders Revoked

ARMSTRONG, Hiram E., 1st Lieut., Pueblo, Colo.
FRIEDLAND, Joseph D., 1st Lieut., Denver.
HAYNES, Elmer, 1st Lieut., Rusk, Texas.
HAYNES, Henry M., Jr., 1st Lieut., Gatesville, Texas.
HOWARD, Robert Bruce, 1st Lieut., Oklahoma City.
IRELAND, Paul M., Captain, Pueblo, Colo.
McGLONE, Frank, 1st Lieut., Denver.
RIKLIN, Henry Hyman, 1st Lieut., Safford, Ariz.

NAVAL RESERVE OFFICERS RECOMMENDED FOR PROMOTION

The Secretary of the Navy has approved the report of the selection board which met on January 30 to recommend officers of the Naval Medical Reserve Corps for promotion to captain and commander.

Dr. Louis Henry Clerf, Philadelphia, was recommended for promotion to the grade of captain.

The following officers were recommended for promotion to the grade of commander in the volunteer reserve of the medical corps:

GENERAL SERVICE

FREYMAN, John Joseph, Omaha.
GERDINE, Linton, Athens, Ga.
IVES, Warren C., Rockford, Ill.
JACKSON, Harry H., Detroit.
KING, W. Ivan, Dallas, Texas.
McCARTHY, Donald, Minneapolis.
RYAN, Edward Raymond, Milwaukee.

SPECIAL SERVICE

BEAN, Harold Cotton, Salem, Mass.
BURK, Samuel B., New York.
CHANDLER, Loren Roscoe, San Francisco.
COFFIN, Whitman King, Boston.
CUSHING, Edward H., Cleveland.
JOSTES, Frederick A., St. Louis.
KANE, Howard F., Washington, D. C.
KNOWLTON, Don S., Washington, D. C.
LYON, George M., Huntington, W. Va.
McCANN, William Sharp, Rochester, N. Y.
McKENDREE, Charles A., New York.
NEILL, William A., Toledo, O.
POHLE, Ernst Albert, Madison, Wis.
POWELL, Lester Davis, Des Moines, Iowa.
RIVERS, Thomas Milton, New York.
SCHMOELE, John Moore, Los Angeles.
SNELL, Albert Markley, Rochester, Minn.
STEARNS, Albert Warren, Boston.
STRANGE, William Wyatt, Huntington, W. Va.
WESTCOTT, Henry H., Roanoke, Va.

FEBRUARY 7, MORNING

(The Government offered a stipulation entered into between counsel for the defendants and counsel for the Government including the constitution and by-laws of the A. M. A. and the District Medical Society. The stipulation also included identifications of the organizations and defendants concerned; also memberships on staffs of hospitals and committees; also a description of Group Health Association, Inc.)

Evidence on Behalf of the Government

DR. HUGH CABOT

DIRECT EXAMINATION

Mr. Lewin:—Dr. Cabot has been called, your Honor, to give factual testimony as to introductory facts and also to qualify as an expert on certain matters that seem appropriate for expert testimony.

Hugh Cabot said in reply to questions that he is a surgeon, graduated from the Harvard Medical School in 1898 and served fourteen months in the Massachusetts General Hospital as an intern and was licensed to practice in 1899. Before he went into the Harvard Medical School, he attended the Roxbury High School and Harvard University, as an undergraduate. He was given an honorary degree of LL.D. at Queen's University, Belfast, Ireland, in 1925. He went immediately into practice as assistant of his cousin, the late Arthur T. Cabot, and then was appointed instructor in surgery at the Harvard Medical School. Then in 1904 he was appointed surgeon to outpatients at the Massachusetts hospital and went through the grades until he left Boston in 1919; surgeon to outpatients, assistant surgeon, and finally full surgeon. In the Harvard Medical School he was an instructor from 1902 until 1910; then he was appointed an assistant professor and then in 1918 clinical professor. He also practiced privately. He was surgeon to the Baptist Hospital from 1901 to 1919. In the World War he went overseas and joined the British medical service in 1916 and served throughout the war. He was mentioned four times in the dispatches and received the Order of St. Michael and St. George. Then he returned to Boston for a few months, and then in September 1919 went to the University of Michigan as professor of surgery, a full time appointment. Later, in 1921 he became dean of the medical school at the University of Michigan. As dean he was occupied, not only with technical matters of surgery but with school administration and the problems of students' educational requirements. "It took a great deal of time that I should have been glad to use for other purposes." In 1930 he went to the Mayo Clinic as one of the consulting surgeons.

Q.—The Mayo Clinic is the one that is the clinic out in Minnesota operated by the Mayo Brothers, the famous Mayo Brothers?

A.—Yes, sir.

Q.—And what was your capacity with that famous clinic?

A.—I was a consulting surgeon, which meant that I was called in consultation by the physicians in most of the general field of surgery. Most of my operative work was in the field of genitourinary surgery, now concealed under the name of urology.

Q.—But you are, Doctor, a general surgeon, and while you were at the Mayo Clinic you were a consultant in general surgery, but when you actually used the knife your specialty was genitourinary surgery?

A.—Yes.

THE MAYO CLINIC

Q.—Now, I wonder if fairly and properly you could describe the Mayo Clinic to this jury.

A.—The Mayo Clinic was, I suppose, the first private organization which brought together in a very small town, Rochester, a group of physicians, surgeons and specialists, beginning in a small way with Dr. Will and Dr. Charlie. They were the men who built it, or their father—they worked with their father for some years; and I believe the conception of a group, formal group, probably began about 1887. . . . You think of a hospital nowadays as an institution around which physicians in all the various fields are grouped. Here was something which started as a group of physicians, never did own or operate hospitals; which were operated by a separate organization. The Mayo Clinic never thought it was wise to involve itself in the operation, the business operation, of a hospital; though of course the hospital group and the Mayo Clinic were very closely associated. They continued to bring in from all parts of the country physicians from various fields. A good many of the men who were on the staff and remained on the staff were men who came there as youngsters, young physicians, in the capacity of what now would be thought of as interns; then remained on as assistants, and finally were taken on to the permanent staff. Later, when the organization became larger, they brought men from other parts of the country and to some extent from other countries. Then I think a very important development was the establishment there of a fellowship group, in which, under funds which had been saved from the operation of the clinic, they took on an increasing number of young physicians in all of the fields, who must have had not only their medical education but some hospital experience before they came to the clinic, and then remained for a period of three or more years on a meager salary but in theory at least enough to keep them alive; and they were candidates for an advanced degree, generally a master's degree in some field of medicine or surgery or the specialties. Some of them remained there for five, six or more years, and from that group in the later years the many of the members of the staff were selected. . . . The Mayos, being of British origin, were rather kindly to the British, and there were English and Irish and Scotch and many Canadians. . . .

Q.—What would you say as to the professional standing, capacities and reputations of the physicians who are employed in this group?

A.—I think they have enjoyed a good reputation. It would be a mistake to assume that all of the world's ability was centered in that institution, or anything like it, but on the whole they always had a very able, capable group of people.

Q.—How were they compensated, Doctor?

A.—Salary.

Q.—Were you compensated on a salary?

A.—Always.

Q.—And the same thing is true of your other distinguished colleagues there?

A.—Except a group which was always a little vague to us. There was a group of partners and it was a little doubtful just who some of the partners were. Some of us were rather curious. We never did quite know. Of course, the Mayos and some of their relatives, sons, sons-in-law, and so forth. But there were other members and I never did quite know how many partners there were, but it was a small number, and, for practical purposes, all of the physicians in that clinic were on salary.

Q.—How were you compensated when you were dean of the Michigan Medical School?

A.—Salary, flat salary, from the beginning, full time.

Q.—And when you were a professor of medicine at Harvard, Harvard Medical School?

A.—There we were paid chiefly in reputation, I guess. If I remember, I drew the princely salary of \$200. I may have been raised to \$500 at the end. But as far as money was concerned, it would just about keep you in cigars.

Q.—Do we understand, Doctor, from your testimony that you and your colleagues at the Mayo Clinic were engaged in what is known as group practice?

Mr. Leahy:—Your Honor, I object to that question. There is no definition of what group practice is.

Mr. Lewin:—If the Court please, Mr. Leahy discoursed at length to the jury on group practice yesterday.

Mr. Leahy:—If your Honor please—

THE COURT:—I am about to sustain your objection.

Mr. Leahy:—Thank you.

THE COURT:—He named this group. It isn't necessary to classify it.

Mr. Lewin:—Can we have the doctor give it this hideous name, though?

THE COURT:—Well, I don't want to select his language for him.

By Mr. Lewin:

Q.—Doctor, how would you name this practice you were engaged in at the Mayo Clinic?

Mr. Leahy:—I object to that, if your Honor please.

Mr. Lewin:—He would rather have the jury get it from him, if your Honor please.

Mr. Leahy:—Let him tell just what the Mayo Clinic was, how they operate.

THE COURT:—Just let him describe it. He has described the group in a general way.

Pardon me for saying the word.

(There was laughter in the courtroom.)

THE COURT:—Now, I will say to you folks, we want to conduct this trial in good humor and I don't expect it to be carried on like a funeral, or anything of the sort, but, nevertheless, I have my own ideas, which are such that I feel compelled to suppress anything in the way of laughter or outbursts. After all, there must be a certain fair degree of dignity in the conduct of the court and I must insist on it on the part of everybody present.

By Mr. Lewin:

Q.—Dr. Cabot, tell the jury, if you will, what advantages, if any, there were to the fact that you had there a gathering of doctors on a salary.

A.—I think if I may use the word "group"—and I think it is important to remember that the grouping together of physicians for the purpose of effective practice goes back a great many years. It may be said to have begun I guess with the early beginnings of the great hospitals. We saw them in Europe before we saw them here. There were gathered together, for the purpose of treating the indigent, physicians in all of the fields as they existed. In earlier days there was no great distinction between the general men and the special men, but they were gathered together in those hospitals for the purpose of effective treatment. I think we want to remember in the whole development of group practice it began there many years ago, in the great hospitals. Now, as far as my knowledge goes, the Mayo Clinic was the first group which you might call a private practice group. These great hospitals of course were not—the physicians and surgeons and specialists there were not in private practice while they were at the hospital; at least in the earlier days. In later days there were private physicians associated with these hospitals, but in the beginning they would work on charity patients and receive no compensation, no financial compensation; though great advantage of course in association with those institutions. Now, the Mayo Clinic, I think, is the first successful, eminently successful, attempt to bring together in a private institution a group which would cover all of the fields of medicine, surgery and the specialties and have there incorporated the necessary laboratories which are essential to the conduct of the great hospital organization.

Q.—Could they have consultations between themselves, the members of the salaried group?

A.—The advantage at the Mayo Clinic, or any of the clinics, is the same as at the great hospitals, that you have a very close relation with all your colleagues. In normal private practice it may be quite difficult to get hold of your colleagues, but in the hospital, and more so in the clinic, you can put your hand very readily on your colleagues in any field, and in the clinic, which was always chiefly under one roof, it was easy to obtain access not only to all the physicians and surgeons and specialists but men in the laboratory field, the bacteriologists, the chemists, with very great saving in effort and I think with enormous educational value. There in the hospitals, and even more so in the clinic, we all of us kept more or less abreast of the times in fields which were not our own particular fields, by constant contact with our fellows with whom we could talk lightly but very helpfully in keeping abreast of the times.

Q.—Mr. Leahy told this jury yesterday—

Mr. Leahy:—I object.

Mr. Lewin:—It is the basis for a question.

Mr. Leahy:—You are not going to make me the basis for anything.

THE COURT:—It is not the proper way to state the question. I sustain the objection without any discussion.

By Mr. Lewin:

Q.—Dr. Cabot, what have you to say about this, the statement that this expedient of practicing in a group was a new idea of social philosophy which sprang up in 1933?

A.—Oh, that is the time—the interpretation. The grouping for the purpose of more effective practice goes back for a great many years in the hospitals, and the Mayo Clinic, then the developments which took place as a result of the successful operation of that organization. A grouping could not be said to have begun at all recently. It is a more or less steady development tending to fit in with the development, economic, financial and, particularly, the development of medicine in its increasing complications.

Q.—Now, Doctor, I would like to continue a little bit more with your qualifications. Have you been interested not only in group practice but have you studied it?

A.—Yes, sir.

Q.—What kind of studies have you made of it, Doctor?

A.—Well, I have taken the trouble to actually visit and go over the ground with various samples of group practice, and then I have spent a great deal of time in studying their publications, the method of organization, not only in this country but other countries; though nothing precisely corresponding with group practice, I think we understand, is at all common in this country outside of the hospital.

Q.—Have you written any books?

A.—In that field?

Q.—In that field or any field of medical economics, if I may use that term, or the distribution of medical care.

A.—Yes, I have written two books, one published in 1936 under the title of "The Doctor's Bill" and another published in 1940 under the title of "The Patient's Dilemma."

Q.—And have you also written on scientific subjects in your own field of surgery?

A.—Oh, yes. Probably too much. The field of surgery and genitourinary surgery for many years.

Q.—Were you ever editor of any scientific paper?

A.—No, not a paper. I edited a two volume work on urology, known as "Modern Urology," the first edition in 1918, one in 1924 and one in 1936, I think, or 1935.

Q.—Have you had occasion to contribute to medical journals?

A.—Oh, yes. Many papers, sir.

Q.—Could you give the jury some idea of the number of titles you covered?

A.—The last time my titles were totaled up so they could be numbered, there were one hundred and fifty. That was probably some two or three years ago.

THE BOSTON ORGANIZATION

Q.—Doctor, have you had any experience in prepayment clinics where the patients who belong to the clinics are entitled to the medical services and pay regular dues in advance, and then are entitled to receive treatment from a group of doctors?

A.—Yes. At the present time I am working with a group of physicians who are arranging for the medical service of a corporation known as Health Service, Incorporated, in Boston, on a prepayment basis. And they arranged with a partnership of five physicians to plan for and arrange for the medical care to their subscribers, and I am the so-called medical director of that partnership.

ORGANIZATION SECTION

JOUR. A. M. A.
FEB. 22, 1914

Q.—Let me be sure I get the picture. How long have you been connected with them as medical director?
A.—Well, in theory a year. We didn't actually begin to treat patients until last May.

Q.—Would you describe that undertaking a little more fully?
A.—The group was started by a group of people in Boston, none of whom were physicians but who were impressed by the fact that there was a considerable number of people in the community who, if they could obtain their medical care on a fixed prepayment basis, should be able, if the plans were worked out satisfactorily, to obtain their care within their rather modest incomes. These people were all lay people and represented the general public. After a good deal of study, of which I know nothing, they came to me among—along with four other physicians, and asked us if we would undertake to plan for the medical care. We agreed and a partnership was formed of five physicians. Do you care to have the names?

Q.—No, I don't think that is necessary.
A. (continuing).—who represented medicine, obstetrics, surgery and diseases of children. They undertook to arrange for a planned medical care and to associate with themselves other physicians. I think perhaps the most striking thing about this organization was that from the start we tried very hard to get this thing to work with the least possible disturbance of the normal arrangements of private practice. What I refer to is the associated physicians, of which there is a considerable group, to carry on their private practice and to see their other patients. Health Service, Incorporated, as they see their other patients. It was our notion that if a sufficiently large group of physicians was included, in this way they would be able to do this work without disturbing their normal relations and thus fit into the present though probably changing pattern of medical practice.

Q.—How did the partnership which composed the professional group receive its compensation?
A.—As partners there we received no compensation; let us say, for our administrative work. In so far as these partners act as consultants, they receive their compensation just as do the other physicians. They are on exactly the same basis.

Q.—Is there a contract in existence between the medical group on the one hand and the business side on the other?
A.—Oh, yes. It is an imposing document; which doesn't mean anything to me at all.

Q.—Would you say by reason of that you were engaged in contract practice?
A.—I would suppose so, the perfectly definite contract between the corporation and the partnership.

Q.—Now, can you describe the group of patients which you serve and the extent of care which you attempt to give them?
A.—We undertake—

Mr. Leahy.—Pardon me. I want to say for the record we will admit the doctor gives the very best of care in the world to his patients. In the economy of time, I don't know why it is we are going so far afield.

Mr. Lewin.—The reason we are going into this is partly because of Mr. Leahy's opening statement. This gentleman is to be qualified on group practice and on prepayment plans and he is going to state the advantages of it.

THE COURT.—Mr. Leahy was stating his defense. You are now proving your case in chief. It isn't the usual time. I will give you a chance in rebuttal.

Mr. Lewin.—Your Honor, the indictment lays the foundation for just this testimony.

THE COURT.—That may lay the proper ground. Mr. Leahy's statement was his defense.

Mr. Leahy.—Your Honor, the indictment gives nothing about Dr. Cabot's service.

Mr. Lewin.—Oh, yes. All of that has been fully argued.

THE COURT.—Well, I don't care. But we have a long trial before us at the best and we don't want to go any further afield than is necessary. It seems to me the doctor's knowledge of this one particular institution is hardly relevant.

Mr. Lewin.—He is going further, your Honor.

THE COURT.—Well, put another question.

Mr. Lewin.—Your Honor's ruling is that he cannot describe the group in this particular thing he has had experience in for years?

THE COURT.—I will permit it if you will do it differently. May I suggest, without any criticism of the doctor, that he answer that question and then not go off into other matters. If you will put your questions so as to keep things going, we will probably save a little time.

By Mr. Lewin:

Q.—Dr. Cabot, will you tell this jury briefly the character of the group that is served, the patients, and the extent of care that you attempt to give them?

A.—The group is limited only by the statement in the agreement between the corporation and the subscriber that the family income shall not exceed \$2,500. There is no other limitation. The great thing is complete medical care, including special care when that is necessary, but not including hospital care which he could obtain in any other way.

Q.—Do you give them a physical examination before admitting them to treatment?
A.—There is admission by groups and as individual subscribers. The individual subscribers are required to have a physical examination. The groups are not.

Q.—Can you tell the jury the purpose of requiring the physical examination?
A.—To be sure that we get a reasonable cross-section of the community and do not become overloaded with people who are already ill, old or what the insurance people call bad risks.

Q.—Doctor, tell the jury something about your membership in medical societies, will you?
(Dr. Cabot listed his memberships.)

Q.—Are you still a member of the American Medical Association?
A.—Oh, yes.

Q.—Have you ever participated in the affairs of the American Medical Association?

A.—Yes. I was a delegate from Massachusetts to the House of Delegates. I am a little vague about it; I think it was about 1910 or 1911, though it may have been 1911 or 1912. Then I was the chairman of the Section on Neurology in 1916, but unfortunately I was overseas in that epochal disturbance and did not serve.

Q.—Dr. Cabot, with that background of experience I am going to ask you if you will describe to this jury the extent and care of medical and surgical practice around the time when you began. Later I am going to ask you to contrast that with the character of medical practice and surgery practice as of today. First, will you describe generally the character of medical practice some decades ago?

(Dr. Cabot described exhaustively the difference between medical practice 1890-1900 and that of today.)
Q.—Will you describe the typical physician's equipment of those days?

A.—It was very much simpler than it is today. The origin of the black bag was so commonly associated with the practicing physician—he had to have a relatively small number of drugs; he had his thermometer; he had his stethoscope. If he were doing obstetrical practice he might keep in his bag his obstetrical equipment, or he might take it only when he was actually going to use it. It was common for physicians of that day to carry a little surgical case which contained some forceps and a knife or two, some ligatures and scissors with which he could do small emergency operations. But a relatively simple equipment would enable him to deal with most of the situations that he was faced with.

Q.—Was the use of x-rays for diagnosis common then?
A.—Oh, no, sir. It began in my day in the medical school, and it was still in the experimental stage until—well, after the turn of the century.

Q.—How extensive was the knowledge of diseases and how extensive was the treatment that was accorded to disease after it was found, in those days?

(Dr. Cabot then contrasted diagnosis and surgery in the two periods. In reply to questions he defined the basic sciences.)
Q.—Can you compare these advances in these various sciences in the last four decades, let us say, with advances in such sciences and in the care of health preceding that period?

A.—Well, it is possibly true that the advances in the last forty years have, in their net value, been almost equal to the bulk of previous knowledge.

Q.—Where does that leave the modern doctor, Dr. Cabot? Are you able to carry on a busy practice and to have accurate knowledge of all these modern sciences in their application to the treatment of diseases?

Mr. Leahy.—Pardon me, Doctor. I will have to object to the form of the question, if your Honor please, because we really do not know what he seeks to elicit. He says "Are you able?"

Mr. Lewin.—I would like to know whether he is able, and then I will go a little further and ask him if anybody else

THE COURT:—If it is to be followed up, I see no harm in it, Mr. Leahy.

Mr. Leahy:—Are you reframing the question as to whether the doctor is able—

Mr. Lewin:—If he is not able, I don't know anybody who is.

Mr. Leahy:—I am happy to hear you talk, and I will listen.

Mr. Lewin:—You are going to hear a lot.

THE COURT:—Let us get along.

The Witness:—The mass of knowledge which should be available for the treatment of disease is today entirely beyond the grasp of any one person. It was possibly within the grasp of the physician half a century ago, but increasingly it has become impossible for any one physician, particularly if he is engaged in reasonably active practice, to have even a bowing acquaintance with many of the special developments which are of real importance and essential importance to the patient.

SPECIALIZATION

By Mr. Lewin:

Q.—Would you describe to the jury the extent that specialization has entered the field of medical and surgical practice now?

A.—It is very great and it is steadily increasing. Today we have among the specialized people the general consulting physician and the general consulting surgeon. Forty or fifty years ago they could fairly well cover their respective fields, but now the specialists in the subdivisions have made that impossible. There is probably no general consulting physician today who does not require the services of experts in their fields. Experts in diseases of the eye, ear, nose and throat are common enough. Experts in diseases of the heart and lungs, experts in diseases of the gastrointestinal tract and experts in diseases of bones and joints. Then, on the surgical side the technic of surgical operations has become so developed that it is almost impossible for any one surgeon to cover the whole field, even leaving out the special senses. So that the general surgeon or the general physician today requires constantly advice from his more specialized brethren.

Q.—Does he require consultations?

A.—Yes.

Q.—Now, has there been any change during that period in the way in which specialists are made?

A.—Yes. Forty or fifty years ago, as the specialties began to develop, there were always people who had been engaged in general practice and then found there a liking to develop a narrower field. That was chiefly made possible by their work in the great voluntary hospitals. But until relatively recently, twenty years ago, most of the specialists had been general practitioners in one branch or another. But more recently the length of time involved in medical education has become such that if men left medical school and the hospital and then went into general practice, and then, having had a view of the field, went back to train themselves and be trained as specialists, they would be almost middle aged before they got back. So it is not very feasible.

Q.—So that you would say it is now common practice for a man leaving his university to enter at once into a specialty without going through the general practice?

A.—Yes; it is very common practice. They commonly take one or perhaps more years in a hospital, in the general field. Then if they propose to practice general medicine they will carry on another year. Otherwise they will begin at that point commonly enough to train themselves in a special field, which frequently runs from three to five or more years.

Q.—What, in your opinion, is the chief cause for this great increase in specialization?

A.—The increase in the essential knowledge. You could not possibly go on without specialization. Of course that is in no way peculiar to medicine.

Q.—Doctor, I wonder if you could tell us of the advances, if any, there have been in the education of doctors and in educational requirements that one must fulfil in order to be a doctor?

A.—At the time I graduated, in 1898, at the Harvard Medical School, which was one of the older and well thought of medical schools, there was only 10 per cent of the students that had any college education at all. The great bulk of the students came to the medical schools of the country, in the middle nineties, from high schools. About the time of my graduation, or within a few years, various universities began to require more or less college work, and the thing went on, not steadily but progressively, up to the present time, where all of the recognized medical schools of the country require at least two years of college work before they will consider a candidate for the medical school.

A large number of medical schools take four years of college work. There is another group, mostly, I think, in the state universities, which have a combined degree. They can take three years in a literary college and four years in the medical school and get a baccalaureate degree and a doctor's degree. So at present it has come about that, while a student may be a candidate for a medical school with only two years' college training, the majority, I think well over 60 per cent, or perhaps more than that, have either four years of college work or this combined degree, so that they take either seven or eight years before they obtain their degree in medicine. Then you will have to add to that the requirement of many states, which is accepted by practically all students, that they shall have some hospital experience. Many states require that before admitting students to examination for license. That practice is increasing, so that at the present time many students may spend nine or ten years in preparation for their life work.

Q.—What is a graduate doctor usually called when he is gaining his initial hospital experience?

A.—They are called interns during the earlier time. Then, as they carry on, after they have been with the organization a year or two, they are often spoken of as residents. In any case they reside more or less at the hospital.

Q.—What can you tell the jury in regard to the extent of equipment that a modern doctor must have, contrasted with what he had back in the days of the little black bag?

A.—Well, he must have, or have access to, all of the methods of modern diagnosis. In the earlier days perhaps he did his own laboratory work as far as it was necessary, made simple examinations of the urine and of the sputum. Today there are very few physicians who do that. They must have access to a laboratory either at the hospitals with which they are associated or a private or commercial laboratory where these examinations are done for them. But if they are in normal private practice and treating patients in their offices they require more equipment than was required in that earlier day, particularly because of methods of accurate diagnosis requiring electrical gadgets, and so forth, which are very assential to accuracy. But, unfortunately, they are very expensive.

Q.—I was going to ask you if an x-ray machine is an expensive piece of equipment.

A.—Oh, very. But very few private practitioners would be required to have an x-ray machine. They would use that of an expert in the vicinity.

Q.—Do I understand, then, that they would send the patient to another doctor who has an x-ray machine?

A.—Yes.

Q.—Could a number of doctors use the same equipment feasibly?

A.—Oh, yes. That is one of the important points in the grouping together, which goes back to the days of hospitals when one set of physicians used the rooms in the morning and another set in the afternoon. In any group you can consolidate office space and save enormously on equipment, and you can make the office space and the equipment work eight or ten or twelve hours a day instead of having a three or four hour day. Great economy there is possible.

Q.—Could they, by the same token, economize in having a common laboratory and common technicians to operate the laboratory?

A.—If the extent of their work is sufficient there are great possibilities to be obtained there in the saving not only of time but of expense. A well organized clinic, such as the Mayo Clinic, though there are many others, is likely to have its own laboratory, and they can get their laboratory work done not only more promptly but equally as efficiently and much more cheaply by keeping the thing working a twelve-hour day.

Q.—What kind of equipment, generally speaking, would a clinic need in order to render complete medical care except for the hospitalization?

A.—Assuming that they did not use the hospital laboratory, they would have to have the laboratories of pathology and bacteriology and medical chemistry available at their hands. If their association with the hospital was quite close they might use the same organization.

HOSPITAL ORGANIZATION

Q.—I wonder if you could describe briefly to the jury the way in which the modern large hospital is run and how it is governed and of what it is composed?

A.—Normally the hospital is run by a board of trustees who are laymen. If it is a tax-supported hospital, a municipal hospital of any kind, it may have an elective board or it may

ORGANIZATION SECTION

Jour. A. M. A.
Feb. 22, 1941

be an appointive board. But the governing board is, as a rule, a lay board, sometimes with one or more physicians to advise the board on details. They then must have an administrator. He used to be known as a hospital superintendent. I think they now like to be called a hospital administrator—whose business it is to carry on the complicated machinery, because in some aspects a hospital is a hotel on one side and a highly technical medical job on the other. The appointments to the staff are ordinarily made by the governing board.

Q.—Appointments to the medical staff?
A.—To the medical staff; yes. But of course the administrator will have to have his assistants under him. The medical staff is ordinarily appointed by the governing board with a varying amount of advice from the administrator.

Q.—Who directs the purely medical affairs of the modern hospital?
A.—The staff.
Q.—The staff of doctors?
A.—Yes. They are divided up as a medical staff and a surgical staff. In large organizations both of those staffs will be subdivided under the specialties, and those staffs will have their own group meetings.

Q.—You are speaking of what is known as the regular or attending medical staff?
A.—Yes.
Q.—Does the hospital today usually have another medical staff?

A.—Yes; a relatively modern development and one of essential importance is that they have a regular staff whose responsibility for the care of the patients who are indigent or partly indigent and who are a direct charge against the trustees of the hospital for whose care they must provide. Then they commonly have what is often termed a courtesy staff. That is to say, physicians who have no duties in the care of charity patients, but who bring their own patients to the hospital and for whom the hospital must assume some responsibility in regard to their capacity and abilities.

Q.—Both of those staffs, I take it, are elected by the lay board of trustees usually?
A.—Yes; though I suppose in practice the members of the courtesy staff are picked out by the regular staff and recommended to the trustees, and the trustees, I take it, would hardly concern themselves with matters of which they could have little knowledge.

Q.—Generally speaking, is it difficult for a graduate doctor who has been in practice and who has had internships and that sort of thing to get courtesy staff privileges at hospitals?
Mr. Leahy:—I object to that question, if your Honor please. I do not think that is a proper subject for expert testimony.

THE COURT:—Will you repeat that?
Mr. Lewin:—I asked Dr. Cabot as an expert whether, in his opinion, it was a difficult thing for the ordinary graduate physician who had internships and that sort of thing to get a courtesy staff privilege at the hospitals.
THE COURT:—He may answer.

Mr. Leahy:—Exception, if your Honor please.
A.—No; hardly a matter of difficulty; but yet the extraordinary situation prevails the country over by which a physician licensed to practice by the state or territory, as the case may be, is still excluded from hospitals. That is, I think, a most unfortunate condition, because today I think it may be stated dogmatically that it is impossible for a physician to give the best medical care if he cannot take his patients to a hospital. He can, of course, send them to a hospital with a break between him and the patient; the patient goes to the care of somebody else. It is a very anomalous situation by which a physician, many physicians, licensed by the state, authorized by the law to practice medicine and surgery, can still be excluded from the use of a hospital without which their practice is not as good as it could be. It is very serious, I think.

By Mr. Lewin:

Q.—In your opinion, what should be the standards that should govern the admission of a doctor to a hospital, who is licensed and has had training?
A.—I see no avoiding the conclusion, Mr. Lewin, that every physician licensed by the state must be assumed to have the capacity requisite in a physician, and that he ought therefore to be potentially a proper person to have on the staff of any hospital. It must always be true that there are second-rate and incompetent people in the medical profession, just as there are in any other field. But I think they should be selected for any hospital staff by a method of trial and not excluded for any reason whatever. To undertake to say that a given physician is not a competent person to be admitted to a hospital for the

care of patients seems to me to run counter to the fact that the state has given him a license to practice medicine. Then another organization, not a state organization, undertakes to say that he may not do so in the most efficient way. I think the selection and the exclusion of the incompetents should be made by admission to the hospital staff, then bringing them along, if they are younger men, as all younger men are brought along, under the supervision and advice of their elders, and with the possibility that they are incompetent or dishonest, of excluding them. I do not like the notion that there can be physicians licensed by the state who are forbidden to practice medicine in the proper way.

Q.—After you have given this licensed physician a trial, I understand you to say that you would exclude him if he turned out to be incompetent?
A.—Yes.
Q.—Or dishonest?
A.—Yes.

Q.—Are there any other standards that ought to operate to exclude him?
A.—Oh, I think so. I think that many physicians applying for a hospital will be people of limited ability; that they should be admitted to the staff only to do the more simple things. Take the surgical staff, for instance. They should at the beginning be allowed to do only the more simple and safe operations. As they go on demonstrating their capacity under the supervision of the senior staff they should be allowed to do more and more. For some of them there would obviously be a limit beyond which they ought not to be allowed to go; they are not of the caliber that can take on the difficulties and responsibilities and the tragedies of major operative specialties, for instance. They are not built that way. But they ought to be allowed in the hospital to do those things for which they have demonstrated a capacity.

Q.—Those standards you have described go to the professional ability of the men?
A.—Yes.
Q.—What ethical requirements or standards should there be, in your opinion?

A.—I suppose, the ethical requirements of the general population. You don't want a crook around the hospital any more than you would want him anywhere else. A person who cannot live up to the ethical standards of society is no person to have around a hospital.

Q.—Are you defining ethics in answer to that question, Doctor?

A.—As rules for the conduct of life, sir.
Q.—Does it have a moral significance?
A.—Oh, very clearly.

Q.—Does it embrace economic views or practices?
A.—Oh, I don't see how it could. I may believe in free silver, but I don't think that that makes me necessarily a good surgeon.
Q.—Or necessarily not a good surgeon?

A.—No.
Q.—Has there been any increase in the use of hospitals in this period of four decades that we have been discussing?

A.—Oh, very great. I can use my own experience. When I was first practicing with my cousin we practically did no operations on private patients in hospitals. They were all done at patients' homes. His charity patients he saw every day at the hospital, but not his private patients. The operations were time consuming because we had to prepare for them. We invaded the house with assistants and the nurse and largely disrupted its economy and did a good deal of damage to it on a fact, was that you were turning the house into a hospital. As people became less fearful of hospitals and the whole performance took a great amount of time. What was happening, got rid of the notion that hospitals were places where a good deal went in and a good deal less came out, they found it was better economics to hire a piece of the hospital for the purpose rather than to turn their homes into a hospital. And today severe illnesses and surgical operations, except the more trivial ones, and a great deal of the obstetrical work is done in hospitals, because it is better done there. The physician and the surgeon have the equipment at hand and there is a saving of expense as well as a saving of time. Of course, not long before the days that I am telling you about, hospitals were the most dangerous places in the world for surgical and obstetrical operations. Even in our early days our incidence of infection was considerably less in private homes than it was in public hospitals.

Q.—Now, Dr. Cabot, you have told us of the longer period of education that is required in these days in comparison with the former days when you came to the profession, the expensive diagnostic and therapeutic equipment that is now necessary, the longer and more accurate diagnosis and treatment accorded in these days, the increase of specialization which you say has resulted and the increased use of hospitals. What have you to say about whether or not the cost of adequate medical care has increased during this period that we have been discussing?

A.—Of course it has. It has increased enormously and inevitably. What the patient is getting today is something that is enormously better but, inevitably, much more expensive than he got or could have gotten forty or fifty years ago. The cost has risen with the improvement.

SERVICE TO VARIOUS GROUPS

By Mr. Lewin:

Q.—And would you just state briefly the basis for that opinion?

A.—Well, I suppose my own experience; what I know from observation as to the costs of care at an earlier day and what I know as to it now. At an earlier day where there was illness sufficiently serious to require hospital care, the hospital charges were not high; as a rule considerably lower than today. There was less special nursing which today has become very expensive; there was less expensive medication. Just as an example, in some diseases, pneumonia for instance, in its treatment today, oxygen may be required which might become very expensive; come to several hundreds of dollars for a case of pneumonia. And then there are the laboratory investigations and studies, of which x-ray is typical. You must have x-rays and inevitably they are one of the most expensive features. So that the hospital cost of hospital care is very much greater. Now, the cost of care to patients who are not required to go to the hospital has risen only in the nation to the fact that the physician himself is under greater expense. What you may call his overhead expenses are very much greater and, obviously, he must collect from his patients enough to pay him a reasonable income.

Q.—Then if you have to use more than one physician, the person who uses those physicians has to pay multiple fees?

A.—Yes, and for consultations; consultations today are and should be very much more numerous than they were, and each one of these people must be compensated. The consultant having special knowledge and seeing a great deal fewer patients must have more for the consultation than the physician who sees the patient in his office; and therefore the charge for consultants, if they are used to the full extent that it is to the interest of the patient to use them, enters very largely in the bill.

Q.—I think you testified that group practice plan, the one with which you are associated, limited its membership to persons with family incomes of less than \$3,500 a year; is that right?

A.—Yes.

Q.—Have you in your studies and writings on these subjects had occasion to explore the question of the effect of these increased costs on groups enjoying that amount of income?

A.—Will you repeat that, please?

(The pending question, as recorded, was read by the reporter.)

By Mr. Lewin:

Q.—That is, less than \$3,500 a year for families?

A.—Yes.

Q.—What effect have these increased costs had on the amount of care those people received?

A.—Of course, that category is composed largely of people of considerably less income than that. I myself believe that it is very difficult for the patient with a family to obtain and pay for adequate medical care today on those salaries on the fee-for-service basis.

Q.—What is the fee-for-service basis?

A.—It is that whereby each physician who gives advice in a given case charges his own fee and sets it at what seems wise and proper to him. It is a service wherein each piece of work is paid for.

Q.—What must the person with that income then do in order to get so-called medical care?

Mr. Leahy:—In his judgment.

Mr. Lewin:—Yes, in your judgment, Doctor.

The Witness:—He has three choices in meeting these expenses which he cannot pay. And I was interested to learn recently that in New England over 85 per cent of all moneys loaned by the small loan people was for unpaid doctors' bills.

It showed that these were a very large item. Now, he may do what a great many people certainly do, ask for and obtain less medical care than he feels would be desirable and is in fact desirable, or, he may more or less throw himself on the mercy of his community and accept charity. Now, unless there is provided some other method he is in a bad fix, I think, anyway.

Q.—What other method occurs to you whereby adequate medical care could be provided for that man?

A.—Oh, the method with which I have been so much concerned for many years. That is, a prepayment basis, whereby a considerable group of people band together, make a regular payment on a monthly or other basis they think fit, and then engage the services of a group of physicians for whom this group of consumers, as we call them, can supply a definite income. The subscriber knows how much money it will cost him, he knows how much money he will have and how much money he can pay. Now, if the group is of sufficient size the thing will work in such a way that entirely adequate and very good treatment can be delivered that could not be delivered by a smaller group, but what happens in practice is that the fortunate man who happens to have a little illness in his family pays for the unfortunate man who happens to be badly stricken with unpredictable illness. It smooths out. This practice has the outlines of an insurance feature, though it is not technically insurance as such.

Q.—Why do you say illness is unpredictable?

A.—Because I think you are in the hands of an all-wise and unscrupulous Providence. I don't know how to predict it.

Q.—What is meant by the term "unforeseen incidents of illness"?

A.—This very thing: nobody can tell when your boy of 17 will go out and hit a telephone pole. It is quite unpredictable when that will happen but not uncommon.

Q.—And now, what experience have you had, and what studies have you made, of these prepayment plans, whether they go along with group practice or not, such as you have just described.

A.—Well, in regard to some of them I have actual knowledge by having studied organization and seeing it work, so far as one can understand such things. As regards the others, by study of publications showing how many subscriptions or subscribers they have, what is the nature of their staff and what is the evidence that care on a statistical basis is complete or incomplete, along that line, et cetera. So that as to some I have personal knowledge or its equivalent; as to others it would be dependent on the accuracy of the publication.

THE ROSS-LOOS CLINIC

Q.—Doctor, will you tell the jury which of these plans you have had actual experience with?

A.—I have been very much interested in the Ross-Loos Clinic, largely because it was one of the earlier experiments if not the first experiment of its kind in this country. It was an experiment in the beginning; it is no longer, it is and was on a prepayment basis; and then I watched and have seen over a considerable number of years how—

Q. (interposing).—Now, Doctor, I would like to have you spell the name of that clinic.

A.—R-o-s-s (a Scotchman) and L-o-o-s (a native of California); he may have been descendant from the Indians, so far as I know.

Q.—They are the doctors who founded the Ross-Loos Clinic?

A.—Yes, and they added certain partners to the group as time went on; but still the great majority of the staff is on salary.

Q.—Could you tell the jury a little more about the development of the plan and whether it has had any success or not?

A.—Yes, it was started on the assumption that the world consisted of certain groups of people, and that in the city of Los Angeles there would be those who would be glad to get their medical care by paying so much a year for a guaranteed complete care. It began in a small way. I can't quite recall what group they took in but they insisted from the start that they would deal with groups only, and one of the earlier groups was of teachers; then there was another similar group, and a group of postal employees; and then they went into the various commercial fields. But they insisted from the start they wouldn't take individual subscribers but only people who represented a percentage of an employed group. The subscriber must be employed. He may then bring in his dependents on a very much reduced rate but not the same rate which he paid, but it is for a family of known size—they sometimes remain known for a time—that it is figured about what the net cost will be. Their plan, I think, from the start included hospital care. They had a hospital which they did not own but which

they supplied with patients in such an increasing number that they had a majority of the patients in the hospital; they may have the whole of it.

Q.—By giving the hospital those patients they defrayed the expenses of the hospital, but the hospital remained a local private institution?

A.—Yes. For a good many years they used only one hospital, and I think they had some working agreement with that hospital that all patients would go to that hospital. Now, the thing has spread over a very large area; the city of Los Angeles reaches over a wide area, for miles and miles. They have substations too, now, where they have a physician and a nurse, and a regional office, and patients may go there with conditions that do not require complicated treatment. In other words, it is almost the situation of the general physician, only he is part of the organization and on a fixed salary income. Very early, I think almost at the start, they built themselves a clinical building so that they would have, as has the Mayo Clinic, all their organization collected in one place, so that now although it is spread out into the surrounding country all the important difficult work is done in the clinic building.

Q.—Has this prepayment feature sprung up as a development in social philosophy only since 1933?

A.—Oh, no; the theory of prepayment, of course, goes back into the days of the British Friendly Societies; has been going on for more than a century. It was evolved in cases of large practice, and the principles and theory is present in the various forms of contracts for medical care in this country and elsewhere, and, on the whole, which did a pretty poor job; but the theory of prepayment is very old, not at all new.

Q.—Has the Ross-Loos Clinic been successful?

Mr. Leahy:—In your opinion.

Mr. Lewin:—Yes, in your opinion.

The Witness:—Yes.

By Mr. Lewin:

Q.—What kind of professional reputation has it now with regard to the care that it renders?

A.—Well, of course, that becomes a matter of opinion. I find that many physicians in the neighborhood are inclined to be critical. I find that physicians who come from a distance and stay there and observe their work are inclined to the view that it is very satisfactory. I include myself in that group and think that the care given is, on the whole, something better than good care. Of course, there is prejudice, perhaps, on both sides. I think, on the other hand, that you can rely on the growth of the organization as evidence that they must have been providing a pretty satisfactory article or they would have failed to grow as they have. They are approaching a point now in their growth where I think they would be well advised to take no more patients. I believe there is a size to which any organization can grow where they might get themselves into administrative difficulties which would be very serious.

Q.—What have you to say of the ethics of a doctor who would accept a salary from such a group?

A.—There could be no ethical objection; there couldn't possibly be an ethical objection. The whole civilized world is on salary, 90 per cent of them, anyway. I don't understand that you gentlemen are unethical because you get paid a salary.

Mr. Leahy:—We are lucky when we get paid.

The Witness:—I think so myself. I was on a salary for twenty years until recently myself.

By Mr. Lewin:

Q.—Now, how about being on a salary with a prepayment group: Is there anything unethical about that?

A.—Why, no, of course not. You may think you are gambling, that you may not get your salary; but that is true of all of us. That has nothing to do with ethics; there is nothing unethical about it, certainly.

Q.—What other groups have you had personal acquaintance with?

A.—I have had some experience with the Trinity Hospital group of Little Rock, Ark., which is one of the oldest organizations of its kind in the country. I am not quite sure whether its beginnings preceded the Ross-Loos, but it is a matter of ten or more years ago since it was organized, in any event. I have been interested in observing the success of the organization and it is my opinion that it is extending very good service to those who are treated. And if you can make a thing work in the State of Arkansas it ought to work pretty nearly anywhere.

Q.—And did it work there?

A.—Yes, and it has been for some time rendering satisfactory service.

Q.—And has that both these features: group practice and prepayment, with salaried doctors?

A.—Yes.

Q.—Now will you tell us something about the operation of any other group with which you are acquainted?

A.—Well, there is the Stanacola.

Q.—Where is that, and what is that plan?

A.—In Louisiana, at one of the big plants of the Standard Oil Company; and there the initiative came from the employees in the form of a group which made arrangements to obtain medical services. I am not quite sure, of course, just what part the Standard Oil Company played in organizing the group. The Standard Oil Company, and many other great corporations, have a medical organization for their whole organization, all their various activities; but, as a rule, it is their business to look out for the industrial feature of the company's activities and see that proper care is rendered in industrial compensation cases. But I am not quite sure that some of the officials of that company didn't suggest the plan. Here was a method, the solution of a problem which the companies did not want to undertake. The company, I think, assisted them more or less with the payment of rent and the furnishing of quarters, et cetera, things like that.

Q.—What would be the reason for a company assisting a group of employees in forming one of these medical groups?

A.—There are a good many companies who believe that the really complete and satisfactory care of their employees is to their own interest. Some companies have provided that care without any charge to such employees.

Q.—And would you say there had been a development in recent years toward more and more businesses encouraging plans of that character?

A.—Well, it would be very hard to say whether it was encouraged by the corporations or businesses or whether the initiative came from the people who were employed. Obviously, there must be a pretty large number of employees or this thing cannot be made to work satisfactorily.

Q.—Doctor, what is preventive medicine?

A.—Preventive medicine is that part of the practice of medicine which undertakes to prevent the occurrence of diseases. For instance, it is highly possible to assure that no child or adult would ever have smallpox, simply by vaccination. That is the old preventive. And from then on, the prevention of typhoid fever by inoculation. That was first proved in the Boer War, in 1888 and 1889. That was not known to us because our losses during the Spanish-American War from typhoid were staggering. And some time later, lockjaw tetanus, and then the prevention of diphtheria. It became possible around the early part of this century. Those are notorious examples of preventive medicine, so that diseases which used to take a very large toll of the population now take a very small number, and could take no toll at all, if preventive medicine was entirely carried out for all people.

Q.—Now, if one of these groups undertook to give complete medical care, would the employee or member have the right to this preventive medicine?

A.—Yes. That is one of the features of the prepayment plan, and I think, one of the most important.

Q.—Would you regard that feature as an asset to the employees of the company who were in such group?

A.—A very great asset.

Q.—Why is it an asset?

A.—Because the problem of employees being regularly present on the job is increasingly becoming important, and the employee's value to his employer is recognized as being in proportion to the man's ability to avoid loss of time through illness. That is as to the man himself. Now if the employee is worried because his children are sick that does not add to his ability as an effective worker. It doesn't make him do a good day's work.

Q.—What other groups can you mention, successful groups, of this character?

A.—Of course a group which has been going on for many years is the Endicott-Johnson Company in Binghamton, N. Y.

Q.—What is that?

A.—They make shoes; and for many years, fifteen or more, have offered to their employees complete medical services, for which the company has paid; and they regard that as a good piece of business. It looked pretty expensive to me but very large proportion of the employees use the service, although they are under no compulsion to do so.

Q.—So you would say that there are, if I may say, some producer organizations in these groups and some consumer organizations in these groups?

A.—Yes, as I use the word, "producer" is an organization set up primarily by physicians, like the Ross-Loos group, in

which a group of physicians decided to group themselves and offer to the community medical care on a prepayment basis; then what I call the consumer basis is one in which the initiative comes from the consumer, commonly known as the patient; a quasicorporative arrangement in which a number of individuals form an organization and then proceed to enter into an agreement of some kind with a group of physicians to provide medical care. Those are the two methods by which the thing may be started; and, more or less in the middle, is the industrial establishment for the care of its employees and sometimes for their dependents.

Q.—Reverting now for a moment to the proper standard for admission of doctors by a hospital to its courtesy staff, would there be any reason, in your opinion, for rejecting a doctor to the courtesy staff simply because he was identified with a prepayment plan?

A.—Oh, no, that would be very improper.

Q.—Now, would admission for the patients of these groups to hospitals be an important thing?

A.—Very important; it is essential. No group can properly offer medical care who cannot also assure the provision of hospital care.

GROUP HOSPITALIZATION PLANS

Q.—Are you familiar at all with a group, just a group hospitalization plan?

A.—Yes; they have been developing all over the country in recent years.

Q.—Is there any similarity between the group hospitalization plan and one of these medical groups you have been describing?

A.—Some similarity and some differences. The group hospitalization plan is an arrangement by which the corporation accepts subscriptions and then agrees with the hospital, or a hospital in the vicinity, to hospitalize and accept its patients as hospital patients for a fixed sum per diem for a certain amount of care. For instance, you may have a ward bed at a certain rate; you may have a bed in a three bed room at a certain rate, and so on. Most of those with which I am familiar do not undertake to provide private room care, though you may get it at a moderate additional charge.

Q.—Then a group hospitalization plan provides this insurance feature, or a feature like insurance?

A.—Yes, for hospital care only. It has nothing to do with medical care.

Q.—Is it possible for one of these medical groups to include in its scheme a group hospitalization plan and to have hospitalization facilities for its members, where necessary?

A.—Oh, yes. Ross-Loos has done it from the start and others have from the start included it in complete care. When we talk of it as complete care I think only of the medical care. Yet the bill may be for hospital care as well and really to use the word "medical care," you should include the hospital as well as the medical care, under the agreement with the subscriber.

(Thereupon, at 12:15 o'clock p. m., a recess was taken until 1 o'clock p. m. of the same day.)

AFTER RECESS DIRECT EXAMINATION—Resumed MILWAUKEE PLAN

By Mr. Lewin:

Q.—I would like to ask you whether or not you have any familiarity with the group medical centers at Milwaukee?

A.—I don't think I have enough to express any opinion; I have read their literature but I have not studied it. And as to the group medical center in Chicago my answer would be the same.

SOUTHERN PACIFIC R. R. PLAN

Q.—Have you any knowledge as to group practice in the large railway systems in the country?

A.—I have been somewhat familiar with the system of the Southern Pacific Railroad; with their experience with a large general hospital there in San Francisco. They have very widely scattered physicians all over the system. I have seen it working chiefly in the hospital where the more difficult and serious cases were sent. I used to go there quite often to see Dr. Lathrop Brown, who was one of their medical consultants.

Q.—What type of group practice would you regard that?

A.—That is group practice set up by a large corporation for the benefit of its employees. As I understand it, they don't deal with dependents, but they have a very wide system with railroad surgeons in different centers who can send their patients to the large hospital centers, if they think it necessary.

Q.—Has the railroad its own hospital or does it use private hospitals?

A.—In San Francisco it has a very large hospital of its own; I am not familiar with the situation along the railroad. I suppose they also use private hospitals.

Q.—Have other large railroads any such system with which you are familiar?

A.—I think it has been very common. I know of the Northern Pacific, which is one of the relatively earlier ones. I believe they are more common in the West and Middle West than in the East. I see relatively little of them in New England.

Q.—Would you think there was any justification for calling this type of practice "herd practice"?

A.—No, I don't think so; there is no herd involved.

Q.—Is it orderly?

A.—Oh, I think yes.

ADVANTAGES OF PREPAYMENT PLANS

Q.—Now I wish you will tell the jury in your own words what you regard as the advantages that emanate, if any, from this type of prepayment group practice.

A.—Well, you can divide it into two parts; the advantages which accrue, I think, always to the patient, the subscriber, and the advantages which accrue to the physician. To the patient the advantages seem to be very clear and very important. All of us, I think, with moderate incomes live constantly in dread of severe accident or illness, or prolonged accident or prolonged illness, as likely to entirely undermine our economic security. Here is a method by which that can be determined, under which they can be sure of getting complete care, depending for success only on the individual's ability to select a proper group; and in that connection the patient is confronted with the same problem in making his decision or choice of groups as he meets in his selection of a doctor. In other words, among groups as well as private individual doctors there are those which are very well conducted and others which are poorly conducted. But aside from this, group practice brings within his reach, the patient's reach, a good many articles, I should say, of medicine and medical care which he ordinarily does not get from a private practitioner. I made reference this morning to the question of preventive medicine. On a normal fee-for-service basis it would be impossible or impracticable to stop Jones on the street and say to him "You ought to have your children vaccinated." There is no question about the desirability of that. Yet if Jones said anything at all it would be probably to inquire about the cost, and very likely on finding out that it couldn't be done at a very reasonable expense he would decide to take the chance. He doesn't know what chance he is taking. It is a chance he shouldn't take at all. It is a chance concerning something of which he couldn't have any knowledge. Under an organization of group practice he gets that as a certainty, with his care for diseases, accidents, et cetera, as they turn up, and as a matter of course.

Again, I believe that in two periods of life pretty careful watching is necessary. Anybody will admit that children, in their early days, ought to be carefully watched; yet under the system of private practice we may be inclined to neglect this care which the child should have; you cannot see your way clear to pay for it. That diminishes as you are going through adolescence, and then, after middle life as people begin to walk into the sunset a great deal can be done to keep the machine from actually cracking up, so that they become dependent while still alive. The average man dreads the chance of being unable to work, and unable to earn, and still live. Many would sooner be dead. A good deal can be done by competent supervision to postpone the evil day and prolong man's working capacity. Those, in my opinion, are just some of the advantages from the point of view of the patient.

From the point of view of the physician, the advantages are various: In the first place, I suggested, they have ready access to their colleagues in the various fields of medicine; the specialist. There is no loss of time, no lost motion. They are at liberty to ask for consultations which they might hesitate to ask under normal conditions because of the expense to the patient. Here it is ready and available any time they think it would help them. They are at liberty to turn over a patient for a particular treatment to one of their colleagues without loss of time and without inquiring whether the man, that is, the patient, can afford it. The question of cost is eliminated, which makes the work of the physician easier and permits him many consultations which he could not charge a patient for.

Then I believe it is very important to him, the physician today, this opportunity to keep reasonably abreast of the progress in the specialized fields. He can keep abreast of his own field if he is reasonably industrious, but he falls down in those other

ORGANIZATION SECTION

Jour. A. M. A.
Feb. 22, 1941

fields in which progress is constantly being made, unless he has ready access to, and discussion with, his colleagues. It keeps his knowledge well rounded.

Then I think for many physicians—I suspect for an increasing number as time goes on—the knowledge that he will have a fixed income is not a small matter. Many physicians are in the greatest doubt as to what their income will be: whether it will be sufficient to support their families. From the point of view of the physician I know of no method whereby you can so successfully introduce immediately to the practice of medicine the young man as he comes from the hospital, as that provided by a regular income. It is a normal procedure in hospitals for young men to be selected and for them to be carried on and along until, after they have worked under the supervision of the staff they are given permanent positions. The well trained young physician today is a very capable person as compared with what he was in my day. He doesn't have to learn so much by practicing on the patient as he has had his experience before starting out, but he is likely to have in the earlier days a great deal of spare time which his patients don't demand, and he has to use it. I have seen a great many young physicians who have gotten into very undesirable states of mind because they have never enough work to do. They have an expensive education on which they have expended their own money or money of their family, borrowed money, and they are not using it. At that age they are people with youth, of great energy and driving power, and they have this talent and ability to employ. I know of no method whereby it can be so successfully used as in group practice.

ADVANTAGES OF GROUP PRACTICE

Q.—Is there any advantage resulting from that group practice in the way of supervision to them from this group staff?

A.—Yes, as I pointed out, the normal procedure of the great voluntary hospitals is to take on younger men, carry them along and, as they show capacity, permit them to move up; if they demonstrate no capacity, are lazy, they slip them out of the way. I am satisfied that the present system in that regard should continue to a certain extent and that supervision should not be lost. To get supervision in a hospital in the old days if there was anybody around who wasn't too busy the young man might get hold of him and do something under his supervision. This method which I speak of of having the younger men come into the hospitals under supervision is the method under which the staff in Mayo and at Michigan have been increased.

Q.—And there are qualified doctors to man group practice, in your opinion?

A.—I think so. I see their correspondence. I have communications from a pretty large number of younger men who want my advice as to how they can associate themselves with group practice, and my opinion as to the various groups.

Q.—Would the quality of medical care given by these groups be inferior to the average care gotten on a fee-for-service basis?

A.—I don't see how you can possibly generalize and say that every organized group would give care superior to the ordinary care, or that the reverse would be true. As I have said, some groups, like individual physicians, dispense an unsatisfactory article and that is no different from the situation which has always existed, in the case of physicians. On the whole it would probably be easier to choose a capable group than it is to choose physicians and then pass on to a variety of specialists.

Q.—So it depends on the individual physician and not on the type of practice in which he is engaged?

A.—I think in a group you stand a better chance of getting a good article.

Q.—Do you think that the fact that the doctors receive a salary has any effect on the working conditions under which they operate, and the quality of care they are able to give?

A.—My professional life has been divided almost exactly into two parts: nineteen years in private, independent practice, and about nineteen years in group practice. I have no hesitation in saying that during the years when I was in the University of Michigan in a group, on a salary and in the clinic that the care that I gave was of an entirely better quality than that which I gave in private practice. I could be entirely frank and honest. It made no difference to me whether I fitted in with the precise whims of the patient or not. I had no fear that if I told the patient the truth I would lose the patient. I think that is more or less in the background of every private physician in his treatment of the patient. We are afraid that if we say to Jones that he is behaving like a jackass, Jones will go to somebody else, whereas in a group you are at liberty to and do tell the patient the truth. I think we are more frank with the patient. Then

I think the ready access to consultants makes you feel very much more secure in relation to your work, so that from my own personal experience I am led inevitably to the conclusion I can give better service in a group than I can as an individual practitioner, even with hospital privileges.

Q.—Would you feel that the doctor who engaged in this type of practice was prevented thereby from having that proper relationship with his patients that he should have?

A.—Oh, no. The relation between doctor and patient is between the doctor and the patient; and doesn't depend on the type of organization. It depends on the wisdom and humanity of the physician and his proper relation to the patient.

Q.—Is there necessarily any lay interference from the laymen who are handling the business side of the group?

A.—Not necessarily. It may occur, of course, and I think profession ought to give its advice very freely to be very sure that the lay management deals with the things with which it has capacity, and leaves to trained experts decisions in matters of medicine and things for which it has special knowledge and ability.

Q.—Is the problem the same as it is with the hospitals where you have a lay board of trustees, and a medical staff?

A.—I don't see any difference; the relationship has gone on over two centuries.

Q.—Is there any more reason for the lay board to interfere in this group practice than there is for it to interfere in the conduct of the affairs of the ordinary hospital?

A.—I think it is possible that there is. I think it is possible that you take a group, for instance, take a cooperative group, which decides to undertake the care of its members through the medium of a group of physicians. Their relation is a little different. It is a little different from the relationship of the hospital trustee, who ordinarily isn't personally involved. I think there is a little danger that the cooperative will think of the medical care as it thinks of buying commodities, and try to get the same article at a little lower price. There is nothing more worthless in the world, and the danger is that the laymen may not recognize that point. That is a point upon which I think well advised bodies of physicians can produce a controlling influence, and should do so.

Q.—Would you regard the fact that the lay president of one of these groups, charged with the business affairs of it, wrote a letter to the hospitals telling the hospitals the group would like access to these hospitals for its physicians, as an example of improper lay interference in medical matters?

A.—No, he is simply asking for his group the ordinary privileges which might ordinarily be obtained for them.

Q.—Would you regard a reasonably worded letter coming from the president along that line as something that was arrogant?

A.—It could have been written in an arrogant way. The mere fact of writing the letter—certainly there wouldn't be anything arrogant in doing that. There is nothing wrong in trying to make sound arrangements with a hospital.

Q.—Would there be anything in such a letter which should offend or be likely to offend those hospitals?

A.—I am inclined to say that if hospitals could be offended that way you had better get new management.

Q.—How about the confidential relationship that exists generally between patients and hospitals? What effect would this group practice on a prepayment basis have upon that situation?

A.—Absolutely none.

Q.—Might there be some danger that the records in the clinics, concerning the patient, might come to light in some way and get into unauthorized hands?

A.—It is practically the same situation that has occurred in the great hospitals for a great many years. Those records are confidential communications, and it is perfectly clear under the law that they may not be at the disposal of anybody else without the permission of the patient. It is precisely the situation that has existed in the hospitals. I am aware that some records have been improperly shown, but I am also aware that private physicians have also allowed access to those records.

Q.—So the group practice on the prepayment basis has no bearing on that problem?

A.—No, I think not.

Q.—While you were in group practice, have you suffered any difficulty in preserving the secrets of your patients as distinguished from incidents of that character occurring while you were practicing on a fee-for-service basis?

A.—No, except this: Occasionally I tried to get a record that they wouldn't give because my name was not on the folder and I had to get another doctor to say I was a proper person to look at it.

FREE CHOICE OF PHYSICIAN

Q.—What is meant in the medical world by the phrase "free choice of physicians"?

A.—I think it is ordinarily used to mean that the individual looking for medical care may take any physician whose services he thinks he desires and in regard to whose capacity he has heard on what he believes to be good evidence that he is a good physician. I take that that is the doctrine of reasonable choice.

Q.—What bearing has group practice on a prepayment basis upon preserving free choice of physicians?

A.—I am inclined to believe that it preserves all the elements of freedom that are worth preserving. Of course, I don't myself believe that the average layman is well equipped to make the choice of physician where there are a considerable number of men available. A different condition may occur where there are not many physicians in the neighborhood, but it is very difficult in selecting a physician for the layman at times to make a good choice, because he has little or no knowledge of the article which he is trying to buy, and there is no satisfactory method by which he can find out its quality. He is depending on what is generally common gossip. Jones says that Brown is a great physician. That is a matter of opinion, and Jones's opinion may not be a very good one. It may be that he has not seen very much of him professionally. It may be that they are two personalities who get along extremely well, that Jones likes him, and so forth, but as a matter of fact Jones may be mistaken in believing that Brown is a good physician.

I doubt myself the accuracy of freedom of choice. I think the average layman will get a better article in group service if he makes his choice in hospitals and groups. Now, in Boston, there are three or four large hospitals between which a patient might make a choice, say the Barstow, and the Massachusetts General. If an individual requires hospitalization he makes a choice from one of those hospitals and having done that he feels that he has put himself in good hands. That has always occurred in the Mayo Clinic. The patient don't go there to see any particular physician. They have reason to believe the Mayo Clinic provides a good article of care and when they get there they normally are assigned to a physician, more or less in rotation, according to who is busy; and always to a general physician. I think that kind of choice which the average layman has is more likely to be right than if he undertakes to seek individual physicians and then the consultant.

Q.—So you don't define this freedom of choice as a capricious one; you define it as being an informed choice?

A.—I should like to provide a situation where it might be an informed choice. I think that they hit upon this method at a time when conditions were not what they are today and that the patient's selection under present day conditions is becoming less and less accurate.

Q.—Even if freedom of choice should be defined to be a capricious freedom of choice, could you tell us whether or not there is anything in group practice which could interfere with that?

A.—No, I don't think so, because in most well organized groups there remains a great deal of choice. Normally a patient is referred to one of the general physicians. Now it is within my knowledge that patients don't always get on with the particular physician. He will say, "I would rather see somebody else." "All right," he is assigned to some one else, or referred to some one else; he has made his choice in that group.

Q.—Well, is he limited to that group? If he desires to consult with another physician outside the group may he not do so?

A.—There is no method by which you can limit him.

Q.—So that he can consult any physician with equal freedom whether he is in the group or out of the group?

A.—I don't see it alters the situation in that regard except, if anything, for the better.

Q.—Would you say that a patient who is told by a hospital that he or she may not have the doctor that he or she wants enjoys the freedom of choice?

A.—No. Obviously not.

Q.—For instance, if one of these members of a group goes to a hospital and is told by the hospital "You cannot have your group doctor, you have got to have our staff doctor," do you think that would be a limitation of freedom of choice?

A.—Oh, quite.

Q.—Suppose a regulation were adopted—

THE COURT:—Mr. Lewin, may I suggest that some of your questions do not seem to do with expert testimony at all, or expert opinion, they are ordinary conclusions on which any person would exercise his judgment. I am only suggesting it to save time. This last question of yours is not one that—it is a matter of understanding of words, ordinary common understanding of words.

Mr. Lewin:—But, your Honor, there is a phrase that is used in this business called "freedom of choice." It is one of the issues here; it was made so yesterday.

THE COURT:—I understand that, but when you ask any person whether there is freedom of choice, that is not expert opinion.

Mr. Lewin:—Well, I think Dr. Cabot would know that and the jury would know which it was.

THE COURT:—We have to leave the jury something to determine.

Mr. Lewin:—Oh, yes. They have the issue here to determine.

THE COURT:—They ought to be able to determine the ordinary meaning of words. We should save as much time as possible.

By Mr. Lewin:

Q.—Dr. Cabot, if the American Medical Association takes upon itself to pass a rule that no doctor shall treat their patients in any of its approved hospitals except its own members, does that or not limit and interfere with the freedom of choice?

A.—It does.

GROUP HEALTH ASSOCIATION, INC.

Q.—Doctor, are you familiar with Group Health Association, Inc.?

A.—Well, I have seen something of their workings. I knew little of the plans in advance, on paper, so to speak, and expressed some opinions, and I did come down here and go over the layout with their staff. I shouldn't regard myself as having a very complete knowledge.

Q.—Could you tell the jury about when you were asked to look into the question for Group Health, and who asked you to do it?

A.—Well, it is hard for me to remember exactly. It must have been in 1937 that I had some correspondence with a Mr. Zimmerman, I think.

Q.—Yes.

A.—And saw him here.

I had some correspondence with a Mr.—well, either Fitz or Kirkpatrick.

Mr. Lewin:—Kirkpatrick.

The Witness: Yes. Then, I did come down here and went around and just saw the staff and saw them at work, one day, and had some discussion at that time with members, I suppose, of the board of trustees.

By Mr. Lewin:

Q.—In which of these categories of prepayment basis does Group Health fall?

A.—I would call it the consumer type.

Q.—Consumer type?

A.—Yes. In which the initiative comes from a group of patients, consumers of this medical care, who then undertake to arrange for a medical group which will do the work.

Q.—Would there be anything wrong or inappropriate in calling it a consumer cooperative?

A.—No. I should think that would be reasonably understood, what it was intended to do.

Q.—Can you describe it a little more fully for the jury?

A.—Well, I am not sure of the accuracy of my information. I was interested more to see whether this outfit with a clinic seemed to me to be doing a decent job than the questions of organization, which didn't seem to be much of my business.

Q.—What conclusion did you come to whether it was doing a good, decent job?

A.—I came to the conclusion at that time that they were equipped to do satisfactory work and that the four or five physicians whom I actually saw at work in seeing patients were doing very well.

Q.—Did you see the clinic itself?

A.—Oh, yes.

Q.—Here in the city of Washington?

A.—Oh, yes.

Q.—Did you inspect this equipment?

A.—Oh, yes. That is just exactly what I did.

Q.—How did you regard its equipment and the layout for its clinic, its facilities?

A.—Well, at that time, as I saw it, with the flow of patients, it seemed to me to be very well regulated, not excessive. I didn't find overcrowded waiting rooms, and the thing seemed to be moving smoothly; and I assume that it was a fair sample of an average day; they had at that time the proper space, and I might say the proper equipment to deal with that group of patients.

Q.—Did they have laboratories and x-ray machines and things of that sort?

A.—Yes.

ORGANIZATION SECTION

JOUR. A. M. A.
FEB. 22, 1941

Q.—And were there doctors on the group staff making common use of these facilities?
A.—Oh, yes.

Q.—On the whole would you say that Group Health Association was fairly representative of the successful group practice on a prepayment basis such as you have described?
Mr. Leahy:—I object, your Honor.

THE COURT:—Objection sustained.
Mr. Lewin:—All right, your Honor.

By Mr. Lewin:
Q.—What would you say the effective group practice on the prepayment basis has done for the cost of medical care to the members of such groups?

A.—If properly organized I think it is certainly a method of diminishing the average cost. In a year it may not diminish the cost, but on the other hand, in another year it may be only a very small fraction of the cost which that patient, or some of them, would have incurred. On the average, taking it over a period of years I am satisfied that that method of payment would decrease the costs of the average family to obtain good medical care.

Q.—Is there any reason why group practicing doctors in clinics of this character will not keep themselves subject to call for their patients, so that they will be available to render care to their patients at all hours?

Mr. Leahy:—I object to that. It is impossible to answer it. This clinic as a 5 o'clock clinic and he wanted this jury to understand that all these groups that his organization opposes quit at 5 o'clock.

THE COURT:—I will permit the question.
Mr. Lewin:—You invited this.

Mr. Leahy:—Well, what are you getting mad about?
Mr. Lewin:—I am not getting mad. If you will permit me, I am just a little indignant.

Mr. Leahy:—Why, this is a very pleasant little gathering. THE COURT:—When I spoke of outbursts a while ago I had in mind, too, this kind.

Mr. Lewin:—I didn't expect to get that kind of objection to a question he brought up himself.
THE COURT:—After I have ruled on a question that ought to end the discussion. I ruled on that question and said that he could answer it.

Mr. Leahy:—Could I hear the question?
THE COURT:—The objection is overruled. It was overruled some time ago.
Mr. Leahy:—May I hear it?

(The question referred to is read by the reporter as follows:)
"Is there any reason why group practicing doctors in clinics of this character will not keep themselves subject to call for their patients, so that they will be available to render care to their patients at all hours?"

THE COURT:—The objection is overruled. I understand that question to mean whether there is necessarily anything in the organization of such a group which would prevent that.
Mr. Leahy:—Was that the purpose of the question?

Mr. Lewin:—Oh, yes. I think that is perfectly obvious, and I am obliged to your Honor for straightening my brother out.
Mr. Leahy:—He didn't straighten me out at all.

THE COURT:—Don't get so mad about it.
The Witness:—Give the doctor a chance.
group, and my experience with the group is, it is easier to get them after hours than it is the practicing physician.

By Mr. Lewin:
Q.—Did you see anything when you inspected Group Health and its operations which would entitle it to this epithet "5 o'clock clinic"?
A.—No.

THE COURT:—I don't believe I would go into that.
Mr. Leahy:—I have no objection.

THE COURT:—I have objected to taking up unnecessary time.
Mr. Lewin:—You? Honor permitted it yesterday.

THE COURT:—I permitted opening statements by you and counsel for the defense, but I don't permit you to take up now the opening statement for the defense. He was stating his defense.

Mr. Lewin:—Yes, your Honor.
THE COURT:—When they have put in their evidence in support of that, then if there is any occasion for rebuttal, we will have it. But we are not going to take up the rebuttal of this case at this time.
Mr. Kellcher:—But, your Honor, don't you think we should be permitted to describe the organization?

THE COURT:—If I thought you should be permitted to describe the organization I would have permitted it.
Mr. Lewin:—I am sorry then. I thought it was proper.

By Mr. Lewin:
Q.—Dr. Cabot, you told us that you for many years have been a member of the A. M. A.
A.—Yes. It must have been forty-two years, I guess.

Q.—What is the A. M. A.?
(Dr. Cabot answered many questions regarding the American Medical Association.)

Q.—Could you name some of the bureaus and councils?
A.—Well, there is the Bureau of Legal Medicine, and I think there is a Bureau of Economics, and perhaps something else put on to it, but it deals with the economic problems.

Q.—Isn't that the Bureau of Medical Economics?
A.—Well, I think so, yes.
Q.—Is there anything novel or laughable about the use of the term "medical economics"?

Mr. Leahy:—I object.
THE COURT:—Objection sustained. I have suggested to you two or three times that I don't think it is proper for you now to enter into a prosecution of the language of defense counsel in his statement.

Mr. Lewin:—Oh, I thought he entered into a prosecution of my language.
THE COURT:—Well, now, I am going to insist that you refrain from that.

Mr. Lewin:—I will.
THE COURT:—And of course my ruling with respect to you will also apply to the defense if they should assume such a method of examination. I don't think it is proper.

Mr. Lewin:—I would like to know whether the term "medical economics" is a term which has been used for a number of years.
THE COURT:—That wasn't your question. You may ask that.

Mr. Lewin:—Yes. I wouldn't say how many but I should think for more than twenty years.

By Mr. Lewin:
Q.—What generally is embraced in the science or study of medical economics?

A.—Well, the economic problems which are peculiarly applicable or more than ordinarily applicable to those problems which come up in the practice of medicine.
Q.—Has the A. M. A. a judicial council?

A.—Yes. Yes.
Q.—What is the function of the judicial council?

A.—Well, they pass on questions referred to them by the state societies in which the state society has taken action and they would like to have action reviewed or approved or disapproved. I don't think the judicial council can deal with problems of an individual except brought through a constituent assembly. Then I think they frequently render opinions at the request of the House of Delegates on problems on which they want an opinion on nonjudicial questions.

Mr. Lewin:—I don't want to offend against your Honor's ruling at all here. I understand this issue is one of substance and not language.

THE COURT:—Just put your question.

By Mr. Lewin:
Q.—I want to put this question to you: I want to know whether the A. M. A. has any control over who remains a member of the local medical societies.

A.—I should not think so in the first instance. The problem of the local medical society is to deal with its own members. Then either party aggrieved I think may appeal that decision to the judicial council.

Q.—And is that decision of the judicial council as to whether that man may remain a member or not, binding on the local society?
A.—Well, I suppose it would be assumed to be.

Mr. Lewin:—Yes.
Now, at this time, your Honor, I would like to offer in evidence a stipulation of counsel as to the introduction in evidence of certain documents. I will ask that that be given a number as an exhibit.

(The document entitled "Stipulation" was marked Government Exhibit No. 2 for identification.)

Mr. Lewin:—I should now like to offer in evidence certain portions of a pamphlet entitled "Proceedings of the House of Delegates of the American Medical Association, the 89th Annual Session held at San Francisco, California, June 1938," and the specific portions I wish to offer in evidence are the printed material appearing on column 2 of page 7, beginning about the

middle of the page, beginning "The general work of the Association" and running through the first two paragraphs in the second column on page 8 in the subject dealing with *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*. I should like also to offer from the same volume the report of the same proceedings offered by the Bureau of Medical Economics. That appears on page 30. And I offer such portions of the document that show the adoption of these reports by the reference committee.

Mr. Lewin:—From this report of the proceedings of the House of Delegates I will read the following:

AFTER RECESS

"The general work of the Association. The year covered in this report"—that is 1938—"of the Board of Trustees has been characterized by a very notable expansion in the activities of the various councils, bureaus and departments of the Association until, at times, available facilities have been seriously strained. A constantly growing interest on the part of the general membership in changing social conditions; increased efficiency of medical organization in counties and states throughout the nation; a more active and intelligent interest on the part of the public in matters pertaining to public health and medical service; legislative activities in the states and in the federal government; the consideration of important questions pertaining to medical education, hospital operations and the extension of public health programs; greater financial and administrative participation on the part of the federal government in public health affairs in states and in communities; proposals for the development of medical and hospital service plans for the benefit of the members of low income groups and actual operation of such plans; and a notable increase in the number of members of the Association together with many other important factors have brought into the headquarters offices a veritable flood of inquiries and demands for information and service. An earnest effort has been made to meet such demands as fully and as helpfully as possible. (58-59) (60).

"Business Operations.

"The official Report of the Treasurer and the official report of the Auditors are submitted to the House of Delegates as a part of this report of the Board of Trustees.

"The gross earnings for the year ended Dec. 31, 1937, amounted to \$1,634,203.74 as compared with \$1,547,218.23 in 1936. Operating expenses were \$982,830.10 as compared with \$909,417.95 in the preceding year. Association expenses including expenditures incident to the operations of councils, bureaus and departments amounted to \$431,635.63 as compared with \$411,028.93 in 1936, while miscellaneous expenses for the year 1937 including insurance and taxes, building expenses and depreciation, fuel, legal services, and the cost of sundry publications amounted to \$218,601.19 as compared with \$209,382.37 in 1936. The net income for the year was \$122,242.92 of which sum \$83,563.74 represented income from investments, so that the actual net operating income was \$38,679.18.

"While only a few of the bonds owned by the Association have defaulted in the payment of interest, there has been a rather serious depreciation in the market value of some of the securities held. The Board of Trustees, the Treasurer and the General Manager of the Association have sought the best available advice with respect to investment of the Association's funds. In accordance with the situation that generally prevails, the average interest return on invested funds has been decreased because of the substitution of securities bearing lower interest rates than those which formerly obtained.

"The payment of wages and salaries, exclusive of those involved in the operation of councils and bureaus, amounted to \$460,182.01 in 1937 as against \$443,693.17 in 1936. Increased labor costs in effect during the latter part of the year accounted for most of the increase in this item, and notification has already been received to the effect that these costs will be further increased during the current year. The cost of paper in 1937 was \$241,663.85 as compared with \$208,922.37 in the preceding year. These costs would have been considerably larger except for the fact that the fullest possible advantage was taken of the opportunity to purchase paper stock before material increased in the market price went into effect. The sum of \$97,274.89 was expended for postage in 1937 as against \$92,123.08 in 1936.

"Fellowship dues and subscriptions paid in 1937 amounted to \$670,170.31 as compared with \$638,243.18 in 1936, the increase being due principally to increased circulation of *THE JOURNAL* and to a rather notable increase in the number of Fellows enrolled. Total receipts from the sale of advertising space in Association publications were \$841,042.57 as against \$780,299.01 in 1936.

"The number of employees at the time of the preparation of this report was 616.

"The purchase of some new machinery and equipment, contemplated when the last annual report of the Board of Trustees was submitted to the House of Delegates, was deferred, in part for the reason that some of the machinery that must be purchased will have to be newly constructed and in part because some of the older machinery which it had been intended to discard was repaired or partially rebuilt so as to extend its usefulness. It will be necessary to install some new machinery in the printing department during the current year. Increased activities of the councils, bureaus and departments of the Association have required the purchase of a considerable amount of new office material (58-59) (60).

"In the Report of the Treasurer and in the Report of the Auditors, submitted herewith, will be found more fully itemized statements of income and expenditure.

"Summary.

"Gross earnings and miscellaneous income were larger in 1937 than in 1936, while operating and miscellaneous expenses were also considerably larger. Income from investments was slightly larger than in 1936. The net income for the year was \$122,242.92, of which amount \$83,563.74 represented interest on investments and \$7,453.20 represented miscellaneous income.

"The Association Building.

"The experience of the past year has fully justified the action taken by the Board of Trustees whereby the entire building was remodeled and two new stories and an assembly hall were added. Better working conditions have been afforded in all departments, and it has been possible by reason of building expansion to bring closer together councils and bureaus whose work is closely correlated and thereby to avoid unnecessary duplication of effort and to increase efficiency.

"Many commendatory expressions have been received concerning the beauty of the Association's building as it now stands. The Board of Trustees would urge the members of the House of Delegates and the members and Fellows of the Association who may find opportunity to do so to visit the headquarters offices to see at first hand the nature and the scope of the work that is being prosecuted there. (59) (60).

"THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

"The place held by *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* in the field of medical periodicals is now so well established that it is unnecessary to offer comment on this point. Nevertheless, the publication has not been static. It has developed a new series of articles on the relationship of the pharmacopeia and the physician. It has continued its campaign against mortality from typhoid and from diphtheria and has reestablished the campaign against Fourth of July accidents.

"The publication formerly called the *Bulletin of the American Medical Association* is now fully incorporated in *THE JOURNAL* as the Organization Section. Here special attention is given to problems of organization, to medical economics, to reports of activities of various councils, bureaus and departments, and to the work of the Woman's Auxiliary. The value of this week by week circulation of important information in the field of economics and of organization for the maintenance of interest of the individual physician cannot be overestimated. Because of the significance of this material, the Board of Trustees would recommend that it be placed in the center of *THE JOURNAL*, and incorporated as a regular feature on medical economics."

I won't bother now to read the other portion of it that I introduced in evidence; and I will introduce now under the same stipulation—will you mark this, please?

(Pamphlet entitled "Proceedings of the House of Delegates of the American Medical Association, the 89th Annual Session Held at San Francisco, California, June 13-17, 1938" was marked Government's Exhibit 3, and received in evidence.)

Mr. Lewin:—I should now like to offer from this volume entitled "Proceedings of the House of Delegates, 1932," certain portions which describe the Bureau of Medical Economics, and the report of the secretary which deals with the Mundt resolution; and the reference committee reports showing the adoption of such reports from the reference committee.

Mr. Lewin:—I should like to offer also certain portions of the proceedings of the House of Delegates of the A. M. A. for the year 1932. That is dealing with the Bureau of Medical Economics, on pages 15 to 18 of that report.

Mr. Lewin:—I withdraw Government's Exhibit No. 4 and my offer to prove it, because I am now authorized by counsel for defense to state to the jury that the following allegation of the indictment is admitted by all of the defendants, without qualification, to be true:

"Defendant American Medical Association maintains a bureau known as the Bureau of Medical Economics which concerns itself with economic organization of the practice of medicine."

Mr. Lewin:—I now offer in evidence, under the same stipulation, excerpts from the Proceedings of the House of Delegates of the American Medical Association, 1931, appearing on page 4 thereof and headed "Bureau of Medical Economics," and also appearing on page 24 thereof, headed "Hospital and Health Associations."

Is there any objection?

Mr. Leahy:—May we approach the bench, if your Honor please?

THE COURT:—Yes.

(Counsel for the respective parties approached the bench and conferred with THE COURT in a low tone of voice.)

Mr. Lewin:—The offer of the excerpts appearing on pages 4 and 24 of Government Exhibit No. 5 is made only as against the defendant American Medical Association at this time.

THE COURT:—It will be admitted on that basis.

(Excerpts from Proceedings of the House of Delegates, 1931, pages 4 and 24 thereof, were marked U. S. Exhibit No. 5 and received in evidence.)

Mr. Lewin (reading from U. S. Exhibit No. 5):—

BUREAU OF MEDICAL ECONOMICS

The Bureau of Medical Economics is just being organized and ultimately will have all available information regarding the cost of medical care. So much misinformation regarding economics is being broadcast that it is certainly our obligation and responsibility to set this right. This means a great deal of study and work and is a task for those who have had much experience in these activities. There are few actual practitioners of medicine on the five year committee on the costs of medical care. The statistical work of the committee has been tremendous, and a great deal of information will be available. It seems to me that a bureau made up of men from the Association would be better able to put the

ORGANIZATION SECTION

JOUR. A. M. A.
FEB. 22, 1941

proper interpretation on the findings of this committee than would those in government and public health work alone. This bureau must have the best man power that can be obtained."

Now I will read from page 24 of the same document (reading):

"HOSPITAL AND HEALTH ASSOCIATIONS

"In reports previously submitted to the House of Delegates, the Council has referred to organizations controlled by groups of laymen, or by individuals, offering medical and hospital service to any who will buy 'membership' and pay a nominal sum each month as 'dues.' Such schemes have been put into operation in various places and have failed within a few weeks or months because of inadequate income or because of failure to render good service. The Judicial Council has regarded these schemes as being economically unsound, unethical and inimical to the public interest."

"Within the last year, some community hospitals have announced their intention to provide medical, surgical and hospital service to families on a flat rate basis. In at least one instance, such service has been offered to families for \$35 a year, irrespective of the number of members in such families. In most instances, certain exceptions are made in that persons with chronic diseases are not entitled to receive the benefits of the plan and obstetric service is not supplied without additional compensation. The members of the Judicial Council doubt that it is wise to lead the people in any community to believe that all necessary medical and hospital service, even though chronic diseases and obstetric care be excepted, can be provided for the average family for \$35 a year. In the cases presented to it the Judicial Council has advised against the adoption of such plans by community hospitals because it is believed that they are not economically sound in that they may be unfavorably affected by conditions entirely beyond control under which contracts cannot be fulfilled. There are other aspects of the matter that readily present themselves for consideration involving the interests of physicians in the community who cannot participate in such plans."

I ask to have marked Exhibit No. 6 the Proceedings of the House of Delegates of the American Medical Association, 1932, from which I offer, as against the American Medical Association alone, certain excerpts headed Bureau of Medical Economics, appearing on pages 15 to 18, and certain excerpts relating to the Mundt resolution appearing on page 40. (Document entitled "Proceedings of the House of Delegates of the American Medical Association, 1932" was marked U. S. Exhibit No. 6 and received in evidence.)

Mr. Lewin:—I shall read from pages 15 and 16.

BUREAU OF MEDICAL ECONOMICS

Purpose, Functions and Method of Procedure

Immediately following the establishment of the Bureau in March, 1931, the director formulated an outline of the purpose, functions and methods of procedure of the Bureau and the phases of medical economics in which work should be initiated as soon as possible, to serve as a guide for both study and administration.

The Bureau of Medical Economics is established to study all phases of general economics that have a bearing on the practice of medicine. In every consideration of medical economics it must be remembered that: humanity; reward or financial gain should be a subordinate consideration. "A profession has for its prime object the service it can render to the practice of medicine is a profession." Although business methods and economic principles are essential to an orderly conduct of the primary phase of the practice of medicine, all such methods and principles must serve rather than dominate the profession, must be secondary to the primary object of the profession, and must conform to the accepted principles of medical ethics.

The principles of medical economics, as they become established, should serve the profession as a sound guide in business and economics; they should never be perverted to defend even the borderline actions of the near charlatan.

The functions of the Bureau of Medical Economics are: (1) to collect, tabulate, study, criticize and prepare for publication and distribution data pertaining to the economics of the practice of medicine; (2) to furnish critical and constructive information and opinions by correspondence on the several phases of medical economics; (3) to encourage the adoption by individual physicians and medical societies of modern, sound, ethical business methods; (4) to urge medical schools to provide medical students with information concerning the economics of medical practice, and an outline of essential business principles which should be incorporated early in individual practice; (5) to develop, ultimately, a consultation service with respect to medical business methods.

The Bureau will endeavor to collect data on the following phases of economics:

- Capital investment in medicine.
- Care of the indigent sick.
- Collection methods and agencies.
- Contract practice.
- Costs of medical education—students' expenditures—complete cost.
- County and state dues.
- Dispensaries and clinics.
- Distribution of physicians.
- Evaluation of medical facilities.
- Evaluation of patient's ability to pay.
- General insurance for physicians.
- Group practice.
- Health and accident insurance.
- Industrial medicine.
- Instruction in medical economics (college and extension courses).

- Malpractice insurance.
- Medical fees.
- Office plans.
- Office systems.
- Panel systems (of foreign countries).
- Physician's income.
- Sickness financing.
- Sickness insurance (compulsory and voluntary).
- Sickness savings.
- Sickness statistics.
- State, county and municipal health department activities.
- Thrift programs.
- Workmen's compensation.

and such other phases of medical economics as may from time to time properly come within the scope of the Bureau's activities.

Opinions on specific, individual or local professional economic problems should be guarded or tentative until a general principle shall have been established to govern in the consideration of each special phase of medical economics. In all phases of the general subject in which the experience of large nonmedical groups has led to the adoption of definite economic policies, due consideration will be given such findings and policies when seeking to establish economic principles for guidance of the medical profession.

Every question pertaining to medical economics will be considered impartially and without personal bias. Courtesy and fairness, with non-medical groups that touch some phase of medical economics, must mark every step of progress.

Policies and principles established after careful deliberation, supported by factual evidence and, wherever possible, by parallel procedures in the business, industrial or commercial fields will thenceforth govern in similar questions and situations.

When considering the economics of medical care, one must make a clear distinction between commercial and economic interests. Commercialism is characterized by: (1) unreasonable fees; (2) alleviation always predicated on cash in hand or no service; (3) unethical tendencies or practices; (4) destruction of scientific motive in both the individual and the profession at large; (5) transformation of the profession into a trade or business; (6) destruction of confidence in the profession; (7) an insidious tendency toward state medicine. Economics as applied to medical practice is predicated on sound ethical principles, constructive and reasonable: (1) Alleviation of suffering, prevention of disease, and reasonable primary obligations of the profession; (2) there should be a just compensation for service rendered; (3) modern ethical business methods are necessary to provide the highest type of service at the most reasonable cost; (4) ethical business methods insure adequate amount and quality of service to indigent as well as pay patients; (5) correct economic measures serve to promote in the profession higher scientific attainments because of greater freedom from financial anxiety.

Detailed methods of providing the most economic medical service to both indigent and pay patients must differ according to local requirements, but the principles and policies governing the application of these methods must be universally applicable.

In many phases of medical economics, physicians must act as an organized group in order to accomplish the most worthy ends. Individual action along these lines will not be as effective or as free from error as collective organized action.

Whenever legislation limits or obstructs the most effective economic and high grade medical service, efforts must be made by organized medicine, after thorough study of the subject, to remove such limitations or obstructions.

New methods of providing medical care should be adopted only after a careful and thorough study of present medical facilities and the requirements for additional facilities. Duplication of effort and overhead expense is a principle diametrically opposed to correct economic methods.

By Mr. Lewin:

Q.—Now, Dr. Cabot, would it be fair to say that the great advances in the sciences that are involved in medical service are solely attributable to the American Medical Association?

Mr. Leahy:—Oh, I object, if your Honor please.

THE COURT:—Objection sustained.

By Mr. Lewin:

Q.—To what body of men, if any, body of men, can you attribute the great advances in the sciences that have brought described, Doctor?

Mr. Leahy:—I object to that, if your Honor please.

THE COURT:—Objection sustained.

By Mr. Lewin:

Q.—Do you know whether or not there is any reason to believe that these group prepayment plans, such as you have described, are designed to destroy the American Medical Association?

Mr. Leahy:—I object to that, if your Honor please.

THE COURT:—Just a moment, Doctor. Objection sustained.

By Mr. Lewin:

Q.—Do you know whether or not, from your knowledge of these plans, they are designed to destroy private practice?

Mr. Leahy:—I object, if your Honor please.

THE COURT:—Objection sustained.

By Mr. Lewin:

Q.—Would you say that a doctor of medicine, Dr. Cabot, was the only person who could tell what the economic standards of practice must be in order for them to be in the public interest?

Mr. Leahy:—I object, if your Honor please.

THE COURT:—Objection sustained.

By Mr. Lewin:

Q.—Would you say that doctors of medicine are the only ones who can judge whether or not medical service is being properly distributed?

Mr. Leahy:—I object, if your Honor please.

THE COURT:—Where do you get that from, may I ask?

Mr. Leahy:—Yes. I got that from the issues presented here.

THE COURT:—You did not get it from the indictment, did you?

Mr. Lewin:—No, sir.

THE COURT:—Objection sustained.

By Mr. Lewin:

Q.—Would you regard it as perfectly proper for one of these group prepayment plans to seek consultations with other doctors outside of the group in serious cases?

A.—Oh, yes. It has been the practice of various groups. I should think it would be highly desirable.

Q.—Would you consider it perfectly proper for them to seek such consultations from members of the A. M. A., even though they might not be members of the particular group staff?

A.—Why, certainly, sir. If they were not members of the A. M. A. they would be very limited in their consultation.

Q.—Why do you say that, Doctor?

A.—Because a vast majority of the physicians of the country are members of the American Medical Association.

Q.—Do you know anything about the attitude of the American Medical Association toward the development of the Group prepayment plans that you have described?

A.—I know what I have seen in the publications of the American Medical Association, chiefly in THE JOURNAL, and what various of their officers have said. I should think, on the whole, they have been inclined—

Mr. Leahy:—I object to anything further. He has answered the question.

Mr. Lewin:—All right.

By Mr. Lewin:

Q.—You say you have observed that attitude. Have you observed any specific instances in which the American Medical Association has manifested an attitude toward group practice that you know of?

A.—I remember that a constituent society, the California society, interfered a good deal with the—

Mr. Leahy:—I object, if your Honor please. There is no evidence that the constituent society of California is the A. M. A., acting as such.

Mr. Lewin:—Oh, yes; we will connect that, your Honor. This witness has already testified that the American Medical Association has constituent societies in every state of the Union. That certainly includes California.

Mr. Leahy:—That is true.

Mr. Lewin:—One of the issues in this case under the indictment is going to be the long-continued opposition to the American Medical Association has exerted against every one of these prepayment plans throughout the United States.

THE COURT:—You are, as I understand it, speaking of the A. M. A. as the managing head. Then does the opposition come down through the constituent elements, or does it originate in the constituent elements? I do not know. Unless you can bring it to the American Medical Association proper, I doubt that it would be competent.

By Mr. Lewin:

Q.—Do you know whether or not the policies of the parent body, the A. M. A., with regard to matters such as these, influence the local societies which are its constituent members?

Mr. Leahy:—I object.

THE COURT:—Objection sustained—if that is an objection. Please make your objections formally so I will know that you are definitely objecting.

Mr. Leahy:—I said, I object, if your Honor please.

THE COURT:—Oh. Pardon me. I will sustain the objection. I only ask that counsel make their objections specific.

Mr. Leahy:—I shall try to do so, your Honor.

By Mr. Lewin:

Q.—You mentioned the state of California. Do you know of any instance in the state of California in which the parent body, the A. M. A., has indicated an attitude toward group practice on a prepayment basis?

A.—Yes.

Q.—I would like to ask you what that attitude was and have you tell the jury about it.

Mr. Leahy:—I object, if your Honor please. That is not the best evidence. If the A. M. A. has expressed an attitude it has done it in some way officially.

THE COURT:—It would not seem to be the best evidence, unless he was there and heard the discussion.

Mr. Lewin:—He says he knows about it. He is a member of the A. M. A. and he is an expert on medical economics and on group practice on the prepayment basis.

THE COURT:—The question is, how he knows.

By Mr. Lewin:

Q.—How do you know about it, Doctor—by study or observation?

A.—By communication with the group which was in disfavor.

Q.—You went out there and inspected the group, did you not?

A.—Not at that particular moment.

Q.—But you had—

A.—I have done so; yes.

Q.—And by reason of your contact with them you gained personal knowledge of the attitude of the A. M. A. toward it; is that correct?

Mr. Leahy:—If your Honor please, the doctor has just told us—

THE COURT:—Are you objecting?

Mr. Leahy:—Yes, your Honor.

THE COURT:—Objection sustained. There is another way of proving the opposition than the method you suggest. Obviously, from what the doctor said it would be hearsay.

By Mr. Lewin:

Q.—Have you knowledge of an incident in Texas?

A.—Yes.

Q.—With regard to the attitude of the A. M. A., the parent body, toward group practice there?

A.—Yes.

Q.—Will you state how you gained that knowledge?

A.—I gained that knowledge as the result of a decision of the Judicial Council made in a case coming from the state of Texas, from one of the constituent societies.

Q.—Will you tell us the name of that case?

A.—I think it is ordinarily known as the Dallas Street Railway case.

Q.—Can you tell us the name of any of the doctors involved in that group practice?

A.—I am afraid I cannot.

Mr. Leahy:—I object. There was nothing said about whether it was group practice or not.

Mr. Lewin:—Oh, yes. I asked him that question.

Mr. Leahy:—No, you did not.

By Mr. Lewin:

Q.—Do you know of any incident in which the attitude of the A. M. A. was manifested towards group practice in Arkansas?

A.—Not specifically, I think, sir.

Q.—In Florida?

A.—Yes, I think so. I think there was a case there, in Miami.

Q.—Have you knowledge of the attitude on the part of the A. M. A.?

A.—I have knowledge only through the documents in the case. I have no personal communication from any officer of the A. M. A. or from the local society.

Q.—What if any knowledge have you of manifestations of the A. M. A.'s attitude toward group practice in Milwaukee, Wisconsin?

A.—Nothing more than gossip, sir.

Q.—Have your own medical and surgical associates in Boston had any controversy with the A. M. A.?

A.—No.

Q.—Or with the local society?

A.—With one of the district—

Mr. Leahy:—I object to that, because it is entirely immaterial, if it was a local society not connected with this case.

THE COURT:—Objection sustained.

Mr. Lewin:—All right, Mr. Leahy. You may cross examine.

Mr. Leahy:—Thank you.

CROSS EXAMINATION OF DR. HUGH CABOT

By Mr. Leahy:

(The cross examination repeated at first the early career of Dr. Cabot. He said the Massachusetts General Hospital was a closed hospital.)

Q.—Would you explain that to us?—because I think the jury would like to know what a closed hospital is.

A.—A closed hospital—the term was used for years, and I think it is still valid—is a hospital in which the staff is appointed presumably by the governing board, and they are the

ORGANIZATION SECTION

JOUR. A. M. A.
FEB. 22, 1941

only people who may practice in that hospital. In the days when I was concerned with it the patients there were all charity patients. There were no private patients in the Massachusetts General Hospital, and I don't think there could be legally at that time. A closed staff was the rule in those charity hospitals in that day.

Q.—I am afraid that the question is liable to come up in the case as to dispensary service. Would you explain that to the jury also, so they will understand what that is as it is connected with the hospital?

A.—It is often referred to as outpatient service and sometimes referred to as ambulatory service. It means patients who can come to the hospital and see doctors on the staff and return to their homes, as opposed to patients who may come to the dispensary and are then sent in to the hospital because they are too sick or require study or for any reason too sick to go home. The outpatients at the dispensary are people who can come under their own power more or less.

Q.—While you were at the Massachusetts General there were no charges made for the services which were rendered to any of the patients; is that the fact?

A.—No, sir; no charges.

Q.—Was it a state institution or a municipal one?

A.—No. It is a very old chartered institution for which there was originally a grant from the state, as the result of which the governor has the appointment of three of the board of trustees out of a group of nine; but except for that grant, along about the Dark Ages, there was no other connection with the state. So the State did have, through the trustees, a minority representation on the board.

Q.—Do you know how it was supported financially?

A.—Oh, yes. By what is ordinarily known as charity, sir; rather "pet charities" of the city of Boston. It was quite a respectable thing to give money to the hospital. It was quite a Mayo Clinic?

Q.—Would you tell us, too, a little more in detail about the (Dr. Cabot again went over many details of organization of the Mayo Clinic.)

Q.—And those who came for treatment to the Mayo Clinic came from all over the United States, did they not?

A.—Quite.

Q.—There was no particular group of individuals which the Mayo Clinic served in any way, was there?

A.—Oh, no.

Q.—In other words, the only group notion about the Mayo Clinic is that it was a group of experts who had established themselves in Rochester, Minnesota?

A.—Yes, sir.

Q.—And to whom those who desired the services of that group of experts came for treatment?

A.—Yes.

Q.—Did the group own its own hospital, Doctor?

A.—No hospital, sir. They never had. For economic reasons they thought it would be better to let that be an entirely separate matter.

Q.—So the service which that clinic renders is medical and surgical service?

A.—Oh, no.

Q.—It collaborates with the hospitals; is that it?

A.—It has its own laboratories on a large scale, sir, that has nothing to do with the hospital.

Q.—But the clinic itself neither owns nor operates any hospitals?

A.—No.

Q.—It has its own equipment, of course, does it not, as you stated, its laboratories?

A.—Yes.

Q.—But there is nothing about the Mayo Clinic which you would designate as a consumer clinic?

A.—Oh, no, sir. That is just what it is not.

Q.—It is strictly, then, in my poor lay language, just a group of excellent physicians and surgeons who are located at Rochester, Minnesota, and who by their skill and by their reputation now have people coming from the United States and perhaps the world to them for treatment; is that true?

A.—I think so. I think it is definitely a group organized for certain purposes.

Q.—In other words, there is not any one who, on a definite, specific, stipulated sum of money, cannot go to the Mayo Clinic and demand service at any time?

A.—Oh, no, sir.

Q.—The Mayo Clinic does do charity service also?

A.—Oh, yes, sir.

Q.—There is another thing that I wish you would explain in connection with some of these questions which are bound to come up in the case, Doctor, and it is just apropos of your answer. What is meant by service for indigents?

A.—It means, I take it, the medical care of people who cannot afford to pay; people who are not paupers, as I used to use the word. That has disappeared now, and they have substituted the word "indigent." But also a group of people who were not paupers, but who had no available funds to pay for medical care. The group has been enlarged, and I think that should be included in the word "indigent," under present conditions.

Q.—Those who reasonably cannot pay for medical care?

A.—Yes.

Q.—Those would probably be described as indigents?

A.—Yes. They tacked on the word "medical"—medical indigents—so as to complicate it a little more.

Q.—Instead of legal indigents?

A.—Yes.

Q.—So we find that the Mayo Clinic does do and did do while you were there what we would call charity work or the care of the indigent?

A.—Yes.

Q.—With reference to the patient who is able to pay, he pays for the service that is rendered to him as a patient by the clinic; is that true?

A.—Yes, sir.

Q.—And that is true of each patient who can pay?

A.—Yes.

Q.—I take it you knew both the Drs. Mayo very well, did you not?

A.—Yes.

Q.—And called them Charlie and Will?

A.—You were not allowed to call them anything else.

Q.—Were they members of the American Medical Association?

A.—Oh, yes.

Q.—Were they presidents of the American Medical Association at any time?

A.—Both of them.

Q.—Do you remember how long ago they were presidents?

A.—Dr. Will was president many years ago. I find it difficult to say, sir, but it was long before the day when I went to the clinic and, I think, before the time when I was at Michigan. I used to come down there, and I think that was after he had been president. Then some years later his younger brother, Dr. Charlie, became president.

Q.—Is there also a son who is still there?

A.—Yes, Charles. He is the son of Charles.

Q.—Do you know whether or not he is a member of the American Medical Association?

A.—Oh, sure fire.

Q.—You also are operating a clinic at this time in Boston, are you not?

A.—I don't call it a clinic, sir, in any ordinary sense of the word. I think of a clinic as a little different kind of organization.

Q.—I will give it the word you want me to call it.

A.—It is a method of offering medical service. I think of a clinic as having to have a building and laboratories and a lot of things of that kind. We have not got to that stage, and may not do so. But at the present time we have a considerable group of physicians who agree to care for a group of patients.

Q.—Do they also practice privately in their profession?

A.—Oh, yes. This would form a very small part of their work.

Q.—Would you describe to us just what your scheme is in Boston, Doctor?

A.—I have already described a part of it. I ought not to duplicate it. The arrangements are arrangements by which we as partners, a group of five of us, ask a group of younger men to work together and ask them to ask their friends, and finally state that we should be glad to take on as an associate physician any physician who is licensed to practice, who is a member of the Massachusetts Medical Society and thus of the American Medical Association, and having courtesy privileges at an approved hospital. The term "approved hospital" means approved by the Council on Hospitals of the American Medical Association. In that way we thought we could certainly secure for our patients a group of physicians not the worst in the state; and then we agreed to accept as consultants in any field anybody who held a certificate from these modern certifying boards which have grown up in the specialties with the approval of the American Medical Association, but not precisely under it. Then of course we also accept as consultants younger men.

could not yet become certified but who within our knowledge or the knowledge of our associates are capable to the extent of their age and size, so to speak.

Q.—Are you at the present time on the boards of any of the hospitals in Boston?

A.—No.

Q.—But you do, of course, enjoy all hospital privileges?

A.—I do not, because since I returned to Boston I have not had occasion to treat patients. If I did I could do it in the Massachusetts General Hospital or the Phillips or the Falkner. But I have not actually made any use of them because I have had no occasion to.

Q.—Do your associates, the doctors whom you have just mentioned to us, also have the privilege of the use of the hospitals?

A.—Yes, because we will not take anybody who has not access to a hospital, who cannot follow his patients to the hospital. We do not believe it is sound practice to have a patient separated from his physician just because the physician has no hospital privileges.

Q.—Are there any other organizations or clinics similar to the Mayo Clinic near Boston?

A.—Yes. The Lahey Clinic in Boston which was, I think, modeled after the Mayo Clinic. I think it is a relatively young organization.

Q.—Do you know whether Dr. Lahey is a member of the A. M. A.?

A.—I think he must be. He is President, and I assume so.

AMERICAN MEDICAL ASSOCIATION

Q.—Now, Doctor, when was it you first joined the A. M. A.?

A.—In June 1899.

Q.—You ought to know something about it, Doctor. You have followed the history of A. M. A. have you not?

A.—I tried pretty hard to, sir.

Q.—You know, of course, about THE JOURNAL, something of which was just read a short time ago to the jury?

A.—Yes. I spend a great many hours reading THE JOURNAL.

Q.—What do you think of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION as a medical journal?

A.—Oh, it is undoubtedly today the most important medical journal in the world, sir.

THE JUDICIAL COUNCIL

Q.—A question was asked you with reference to the constitution of the American Medical Association, and that was with reference to its council, the Judicial Council, and I think you stated that so far as you knew the jurisdiction of the particular council was limited in a sense, as we call it, to sort of an appellate jurisdiction?

A.—Yes.

Q.—It does not originate anything?

A.—I do not think so, although I would not be dogmatic about it.

Q.—Let us assume that a doctor in one of the local county associations were charged and his local county association had expelled him. Do you know whether or not that member of the county association would have an appeal or the protection of an appeal in any way?

A.—I think he would have to go to the state society and then take an appeal to the Judicial Council.

Q.—And that is where the jurisdiction of the Judicial Council comes in?

A.—That is my understanding of it.

Q.—In other words, the member who is charged, before he is expelled, has the protection, first, of his own association, then of the constituent state association and then one further step up to the Judicial Council of the American Medical Association?

A.—Yes.

Q.—In other words, the American Medical Association itself does not originate charges against anybody?

A.—I don't think so, sir.

STATUS OF COUNTY MEDICAL SOCIETY

Q.—Am I right, too, Doctor, from your experience, in saying that the county association is an independent association which governs itself, elects its own officers, has its own constitution and by-laws, of course subject to the medical ethics prescribed by the American Medical Association?

A.—It is subject to its own state control. I take it, first, it is a subdivision of the state society.

Q.—With reference to its own internal affairs, its own local affairs in the county association, it elects whom it wishes to membership, does it not?

A.—Yes; I think so.

Q.—There is no control superimposed by the state association upon the county association with reference to the constitution of its membership, is there?

A.—Yes; I think there is, sir. I think the state association lays down certain rules as to who may be admitted to membership in the county society.

Q.—But within those rules the county association admits as it sees fit?

A.—Yes.

Q.—And then it elects its own officers, does it not?

A.—Yes.

Q.—And it has its own constitution and by-laws?

A.—I would not be too sure. I never saw the constitution and by-laws of the County Society. I guess they have one.

GROUP PRACTICE

Q.—Just a few questions, Doctor, about what was asked you with reference to group practice. How many, in your own experience, would you say there were of these groups—and let us call them consumers—which had been organized, we will say, during the last ten years in the United States? Have you statistics on that at your fingertips?

A.—No; but very few consumer groups, as you and I, I think, are using the term, who were associated in an important way before that time. This is rather a recent development in the group field.

Q.—That is, consumer groups?

A.—Yes.

Q.—And in order that we might not be at variance as to what we are talking about, a consumer group is a group of individuals who buy medical service or are patients or potential patients?

A.—Yes.

By Mr. Leahy:

Q.—Have you any knowledge from your studies as to whether that sort of consumer group practice had been tried abroad in Europe before that time?

A.—I think the principle had been tried though the setup was a little different. A great many years ago, particularly in the low countries, in Denmark and the Netherlands, cooperative groups arranged for medical services, but the thing is all pretty shadowy, pretty old, and largely disappeared. There were some arrangements more recent than that directly under organized cooperatives, but I think they are relatively few and I cannot say I understand much about them. I don't think they are an important economic development.

Q.—And I think you said they were relatively few in the United States also?

A.—I don't think there are many.

GROUP HEALTH ASSOCIATION, INC.

Q.—Do you recall when it was you first saw group health in Washington?

A.—Now, I don't want to be dogmatic about that. I could say roughly.

Q.—Just your best recollection.

A.—Probably in the autumn of '37; it might have been in the early part of '38.

Q.—Do you recall when it was that you first knew about group health in Washington in any way from any source?

A.—You mean this specific organization?

Q.—Yes, this specific organization.

A.—Well, it was certainly during the year '37, not before that.

Q.—Do you recall about how long it was before you came down here that you learned there was such a group?

A.—Probably two or three months.

Q.—And did you learn about it through someone writing to you?

A.—I daresay I heard about it from Dr. Richard Cabot, who had, I think, been down here. I never saw him here. He wrote me about it and thought I would be interested, and would probably want to know about it. I daresay that was the first I heard of it.

Q.—Did you come down here to see the group at the request of someone or at your own choice?

A.—I came at the request of some member of the organization here, the lay organization.

Q.—Do you recall who it was who asked you to come?

A.—At a guess, it was either Kirkpatrick, if that is the right name, or Penniman. I had some correspondence with both those gentlemen. I would not be dogmatic; I am not sure I have the right name now.

Q.—Did you meet whichever one of these gentlemen it was, whether Kirkpatrick or Penniman or who, when you came to Washington?

A.—Yes.

Q.—Do you recall how long you were at the clinic?

A.—Oh, I should say perhaps three or four hours.

Q.—Did you go back the same day you came down?

A.—No, I stayed overnight. I first talked to some of these laymen and then went to the clinic, and then, if I remember correctly we met for dinner and there carried on a discussion, and also later in the evening.

Q.—Did you go very thoroughly into the organization of the group?

A.—I wonder whether you mean of the medical or the business organization?

Q.—Did you go into the business organization at all?

A.—Only so far as to note what their scale of charges was and to come to the opinion that with a reasonably large group of subscribers the amount of money they would have would be sufficient to enable them to carry on.

Q.—Do you recall now as to whether you had any information as to how many subscribers they had at that time?

A.—I remember being impressed by the fact that at that time the number was not large enough to make certain that if it would not grow that it could carry on and render the kind of service intended.

Q.—Did you have any number fixed in your own mind, Doctor, of subscribers which would be the minimum in order for the success of the venture?

A.—I had it fixed in my mind; I came to the conclusion that without something in the neighborhood of a thousand members the fixed income would be insufficient with which to do the job.

Q.—Do you recall what each subscriber was to pay when you were talking to them?

A.—It would be difficult for me to say because I didn't make any mental note of it. It would, however, be right in my mind that they were to pay \$2 a throw, but I wouldn't put very much money on it.

Q.—You mean by that \$2 per month?

A.—Yes.

Q.—You think about \$25 a year per person?

A.—That is the way it lies in my mind; after that it was raised, I think.

Q.—As a result of the inspection which you made at the clinic you thought that about \$25,000 would operate it as it was then equipped?

A.—I didn't put it that way; I didn't figure that out that way.

Q.—Does it work out that way?

A.—Yes.

Q.—You said the irreducible minimum as to the number of subscribers would be one thousand, and the cost of the operation \$25,000 per annum?

A.—Well, I was aware that those things don't start in a vacuum, and you must build them up; and it seems to me, or it seemed to me that they must have a thousand members to enable them to carry on according to the program and not leave them worried as to whether or not they were going to get by.

Q.—Did you at that time go over the equipment; inspect it?

A.—Yes, that would be a fair statement. I went around from one department to another and, comparing it with similar equipment elsewhere, thought it sufficient.

Q.—You were told how the equipment was purchased, were you not?

A.—No, if I was I have forgotten about it; I wasn't concerned.

Q.—Were you told as to where the funds came from to purchase the equipment?

A.—No.

Q.—You were just shown the clinic; you inspected it, and you were told they had a thousand members?

A.—I don't remember that they said they had a thousand members; and I don't think that I said that I did.

Q.—But you concluded they would have to have that number in order to function properly there according to the program which you understood they had?

A.—Just a minute; I think you are putting something in my mouth. As I understand the subscriber, he is the head of the family who then brings in various dependents. Now it is very commonly true that a subscriber pays a fixed sum; then a dependent, usually a wife, pays a somewhat lesser sum; then other dependents who are under 18 pay a lesser sum, and young children a still lesser sum. So I don't understand that it was to be expected that there would be \$25 from every patient; I was talking about subscribers; not patients.

Q.—In other words, the subscribers, or the patients, might exceed the actual number of subscribers?

A.—Yes, as I use the word, that is right. The number of individuals who have care often exceed the number of people called subscribers and to whom the group looks for its moneys.

Q.—Do you recall now whether you went over the plan thoroughly enough to ascertain what a dependent of a subscriber paid at that time?

A.—I think I was told; I don't remember, but I am satisfied it was a lesser sum than the subscriber. I was chiefly interested in ascertaining whether or not a good job could be done there. I am not regarded, myself, as a financier, and do not pretend to know much about the business end of it.

Q.—Did you go into the financial side at all?

A.—Not in more than very general terms.

Q.—Did you meet the doctors?

A.—Yes, I think I probably met all of them; I wouldn't like to say.

Q.—Who was the surgeon at that time?

A.—A gentleman by the name of either Sellers or Selders.

Q.—Did you ever meet him before?

A.—No, sir.

Q.—Did you have any further study made of the Group Health Association here in Washington than that one visit?

A.—Beyond correspondence, et cetera, publications, no. That is the first time I ever went there and looked over the organization, physical plant.

Q.—I take it you had nothing to do with the original formulation of the plant?

A.—Nothing.

Q.—It was a going concern when you first heard about it?

A.—I think it was not quite clear which way it was going; there were some features that were dropped.

Q.—Well, it was operating?

A.—Yes, the wheels were turning.

Q.—When you saw it?

A.—Yes.

Q.—Have you ever been in the clinic since that time?

A.—No.

QUALIFICATIONS FOR HOSPITAL STAFF

Q.—I think you stated something to us today on direct examination, and inasmuch as we are on the subject of hospitals, you stated it to be your opinion, Doctor, as I recall it, that in your judgment any person whom the state licensed, and whom the state declared was capable of practicing medicine, ought to have the privilege of practicing medicine?

A.—Yes, I have felt very strongly about that for a great many years. That is my opinion. I have constantly said so. It has troubled me considerably.

Q.—Do you know of any state, city or hospital where that thought of yours is put into effect?

A.—No, that's it. That's one of the things that trouble me.

Q.—In other words all hospitals do through their local board of trustees make an investigation of those who are admitted to either the regular or courtesy staff?

A.—In the hospitals with which I am most familiar the operation is carried out through the staff. The governing board says, "Now, you look into the qualifications of these people, and if in your opinion they are qualified, submit their names." I think the governing board never undertakes to have any opinion of their own. They depend on the opinion of their staff.

Q.—Now, under your opinion, Doctor, which you state, in your judgment, there is at least a prima facie right in a doctor who has been licensed to practice medicine until he is found to be wanting in some way; as I understand it, that is your idea?

A.—Yes.

Q.—But even under your thought, if you knew something about a doctor which you thought should disqualify him from service in the hospital, or from the right to serve his patients in the hospital, you still wouldn't think he would have the right to courtesy privileges, would you?

A.—That is a little abstract. The question was whether I knew something which would disqualify him. That would depend on what it might be. As to the younger men I might think that by bringing them in and putting them in the staff and letting them develop, that that reason might disappear. I am a great believer in taking them on, putting them on the staff and, particularly, if they are young. Youth, to be young, that is not a fatal disease. Now, men older than that you would have to know something about their capacity.

Q.—Would you think, for instance, that a doctor who had just graduated from—what do you call it? Resident Service?

Yes, just graduated from residency, and been licensed to practice should have the right to practice general surgery of all kinds in a hospital?

A.—Well, it depends on the nature of his residence, but on general principles I should want to have him come in and observe him, and see him function under the supervision of the staff and then give him an opportunity, if he demonstrated the capacity, to be put on the staff.

Q.—Would you think the hospital should give that young man or that person the right to perform any and all kinds of operations?

A.—I should be skeptical about that.

Q.—Wouldn't you want to make some inquiry to determine his fitness?

A.—I should be in favor of giving him a chance to show what ability he possessed, as I have explained to you.

Q.—Well, wouldn't you want to know more about the man? Wouldn't you want to make some investigation; or would you think that it was proper for him to go into the hospital and perform any sort of an operation?

A.—I would be skeptical about that, but I would like to see him in action. Talking about these fellows with others doesn't get you very far.

Q.—Would you let him go in action first, and then determine his qualifications later?

A.—I would let him go into action under wraps.

Q.—What is that, Doctor?

A.—I said I would let him go into action under wraps.

Q.—What do you mean by that?

A.—I would like him to do operations of lesser and moderate severity at first; certain minor operations, standard operations of moderate severity. I should like to know how he actually behaved, before I actually turned him loose.

Q.—In other words, you wouldn't want to give him the privileges of practicing on mankind in order to determine whether or not he was qualified to do so?

A.—No, unless he was a trained man of which I had plenty of knowledge. But there are people who by reason of their residence training are entirely qualified by that training alone.

Q.—Let us assume he was a resident for one year and then had come out with a license to practice. Would you think his license to practice, with an experience of residency of one year would entitle him to the privileges of general surgery in the hospital, or would you put him under wraps?

A.—Put him under limitation.

Q.—Now, you wouldn't think even under your own opinion that the mere license a doctor might possess to practice his profession would entitle him to hospital privileges if there was a grave suspicion as to the legality of his practice, would you?

A.—Oh, no.

Q.—For instance, if you knew there was a question, a serious question raised as to the legality of the practice of a given physician, and you found that the hospital staff had requested that his application be held up until that question had been determined, would you think that was a reasonable act on the part of the hospital?

A.—That sounds reasonable. I don't know what the word "legality" means, as you use it.

Q.—Suppose we are specific: Suppose or assume that the association with which this doctor is connected has been notified by the Federal District Attorney for the District of Massachusetts that they must desist the practice in which they are then engaged, and you know this young man has made an application to your general hospital for hospital privileges, if you were advising the hospital, as a member of its staff and so advised it that they ought to withhold the privileges from this young man pending the determination of the question, would you consider that good advice?

A.—That would sound like good reasonable advice.

Q.—Just what you would do?

A.—Yes.

Q.—Now with reference to one other phrase, and then we will be about through. We have had here asked about "adequate medical care," and "complete medical care." Frankly, I don't know what they mean. Will you tell us?

A.—I won't bite.

Q.—Frankly, I don't know the meaning of those terms. Will you tell us what they mean?

A.—I will not, I don't know what it means. I don't use the words, adequate medical care, complete medical care.

Q.—Well, won't you give us your idea of what they mean?

A.—No, I won't; I don't know.

Q.—You don't know; and I don't know either. I don't think anybody knows.

A.—I will tell you what "complete medical care" is.

Q.—Well, what is complete medical care?

A.—Complete medical care would mean that the care offered by this organization covered the whole field of preventative medicine, diagnosis and treatment in all fields. It is very all-inclusive. It means that there is no condition from which the patient complains that you will not treat him for.

Q.—In other words you think the staff numerically should be large enough so that there will be a man, some member of the staff, competent to handle any and all cases in every field?

A.—If the association says they offer complete care, yes. Now, I know of several organizations that started in on a small scale, who were perfectly frank to say there were certain fields they would not undertake to explore. They made that very clear; they were frank about it and there was no difficulty.

Q.—But exclude those fields?

A.—Excluding those fields, they should.

Q.—Now, in your opinion, would the care be complete medical care if the quality given was not good medical care?

A.—I suppose when I say "complete" I refer to quantity; the question of quality would be another matter.

Q.—You would think there was complete medical care if it wasn't of good quality?

A.—I might regard it as complete. I think the question of quality would have to be separated from the question of quantity.

Q.—In any organization which offers to anybody or everybody complete medical care, if in that care they render the care is not good care, the quality is not good; would you think the organization was operating in the public interest?

A.—It would depend on who said it was not good care.

Q.—I will make it in your opinion. If in your opinion the care was not good, what would you say?

A.—If I didn't think it was good care, I should say "No."

Q.—And do you think that there would be or could be any one else who could determine that question other than a physician?

A.—I would not pick a fool like me: I would pick a much better group of people than that.

Q.—Well, you would pick a good medical man, wouldn't you?

A.—I think I should want a group of physicians, with varying capacities. I, for instance, would be a very poor witness on the capacity or capabilities of an ophthalmologist for instance or of a specialist in certain other fields. I should doubt whether there would be any one physician who could judge the capacity of the group; and I think it is a job for more than one physician, a committee of them.

Q.—In any event it would necessarily be a group of medical men?

A.—Yes.

Q.—Did you have an opportunity while you were here at all to observe the quality of the practice of Group Health Association?

A.—Well, I saw two, if I remember, of the physicians actually examining and treating patients.

Q.—What were they examining for?

A.—One was a pediatrician, and he was looking over children, and he seemed to me to be doing a thorough job of it. Now, I am not an expert pediatrician, but after seeing for a good many years what has been going on I think I would be able to say whether or not he was doing his job in a slipshod, slapdash sort of way, and on the whole he seemed to me to be doing a pretty good job.

Q.—Who else?
